

# Let's stop talking about AIDS

by Simon Watney

Most readers will be familiar with the history of how the Acquired Immune Deficiency Syndrome was first identified in the United States in 1981. Doctors in New York and Los Angeles had independently reported significant clusters of cases of two previously very rare medical conditions—pneumocystis carinii pneumonia (PCP), and a form of cancer known as Kaposi's sarcoma (KS). The only connection between these, and a number of other rare diseases being reported amongst otherwise healthy young gay men, was their known association with damage to the body's immunological defenses.

Because these clusters were first identified among gay men, they were at first collectively described as Gay Related Immune Deficiency (GRID). It was eventually recognised (and not without considerable resistance on the part of some doctors and epidemiologists) that the underlying causes of these clusters of rare diseases was not specific to gay men, especially after it was discovered that the unknown agent (or agents) responsible for them could be transmitted via blood transfusions. Thus, in 1982, the Center for Disease Control (CDC) in Atlanta, Georgia, officially classified the condition as Acquired Immune Deficiency Syndrome, by which name it is still widely described.

The Human Immunodeficiency Virus (HIV), which is responsible for AIDS, was not isolated until 1983, and not made public until the following year. In all of this it is important to remember that doctors, and members of the gay community, were working *backwards* in a *detective* manner, in order to establish the agent responsible for AIDS, and to understand its possible modes of transmission in order to protect people. Thus it was that

The easiest and most logical way forward would surely be to gradually abandon the category of ARC and AIDS altogether and to encourage the adoption of a simpler — and more accurate distinction between HIV infection and HIV disease.

Michael Callen and Richard Berkowitz wrote their groundbreaking pamphlet *How to Have Sex in an Epidemic*, with a preface by Dr. Joseph Sonnabend, in 1983, on the assumption that some sexually transmitted factor was responsible for many if not all cases of AIDS. That was the originating moment of what we all now know as Safer Sex. Nonetheless, even now in 1988, the distinction between HIV and AIDS is still far from universally understood, and AIDS is widely regarded as if it were a single *disease*, rather than a *syndrome*, which refers to a huge range of conditions which may emerge in the wake of HIV infection, and damage to the body's immunological defenses.

opportunity" (horrible word) of damage caused by HIV. It should also be stressed that most of the conditions which may lead to an AIDS diagnosis are present in *all* of us, but are held in check by our immune system.

It is this set of relatively straightforward facts which is difficult to communicate to many people because of the way in which AIDS was first identified and classified back in 1982. Many of the most basic misunderstandings about AIDS stem from a failure by journalists and others to appreciate the sheer diversity of medical experience, and the complexity of issues raised by a syndrome. To describe AIDS as if it were a single

disease is an easy option, but it obscures almost all the real issues faced by individuals with AIDS, and has led to any number of misleading assumptions and ill-informed beliefs about almost every aspect of the epidemic. For example, many people still talk about "catching AIDS", and the belief that there is an "AIDS test" remains unfortunately widespread.

Strong reasons to bypass AIDS

There are thus strong reasons why we should consider following the example of doctors who have bypassed the notion of AIDS, just as AIDS bypassed the earlier classification of GRID. They talk of *HIV infection*, referring to the specific and limited modes of transmission of the virus; and *HIV disease*, referring to the disease of the immune system itself and the wide spectrum of subsequent medical conditions which may arise in the wake of HIV infection.

There is another compelling reason why we should consider this as a significant advance. As knowledge concerning the effects of HIV

## Three ways to be part of the excitement!

Rites invites you to participate in the making of Canada's most exciting gay and lesbian liberation magazine. If you write, take pictures, or can cut and paste — we'd like to hear from you. Here are three easy ways to connect with Rites:

1

### MONTHLY PUBLIC EVALUATION MEETINGS

Rites holds evaluation meetings after every issue on the first Tuesday of the month.

Join us for the next one:

Tuesday April 4 at 8pm  
519 Church Street Community Centre

2

### PRODUCTION — LAYOUT & PASTE UP

More fun than Saturday afternoon art class. Learn hands on how a newspaper is made:

Saturday and Sunday from 1-6pm at the Rites office in the Coach House behind 428 Dundas St. East. The next production dates are: April 22, 23; May 20, 21; June 17, 18

3

### DISTRIBUTION

Now the real fun begins. Envelope stuffing, labelling, sorting and bagging. Mail out takes place the Thursday after production.

grew in the 1980's it became clear that a large number of people with HIV were becoming seriously ill though they did not have illness which are officially classified AIDS. The revision and enlargement of the diagnostic category AIDS by the CDC in August 1987 has not really improved the situation of all those people who still fit themselves diagnosed as people with AIDS Related Complex (ARC) sometimes known as AIDS Related Conditions.

A diagnosis of ARC is in some ways even more difficult for many individuals to live with than a diagnosis of either HIV infection, AIDS. ARC is widely seen as an "in-between" condition, half-way between HIV and AIDS. This only encourages the use of absurd terms like "full-blown AIDS" to refer to people with symptoms of the syndrome, and implies that people with ARC have "half" or "seriously" AIDS!

### A simpler, more accurate distinction

It is clear that nobody set out deliberately to construct this Chink Box of medical categories, with the confusion and misunderstanding which they tend to reinforce. The easiest and most logical way forward would surely be to gradually abandon the category of ARC and AIDS together, and encourage the adoption of a simpler—and more accurate—distinction, between HIV infection and HIV disease. In this way large numbers of people would be spared totally unnecessary stress involved in an ARC diagnosis, which is a cruel and sadistic category which nobody should in future be obliged to identify their experience of HIV disease. This would have the advantage of undermining much of the demonizing mythology surrounding the present classification of AIDS. It would make the task of HIV education easier, and by making the epidemic more comprehensible to many people, might help in the crucial task of preventing further infections, and improving the general quality of life by everyone affected by the consequences of HIV infection and HIV disease.

<sup>1</sup> *The Search for the Virus* by Steve Connor and Sharon Kingman (Penguin, 1987) provides the clearest available account of this history.
