

Summary Remote Sensing Seminar

Lectures in Bertinoro

Paul Menzel
NOAA/NESDIS/ORA

23 Aug – 2 Sep 2004

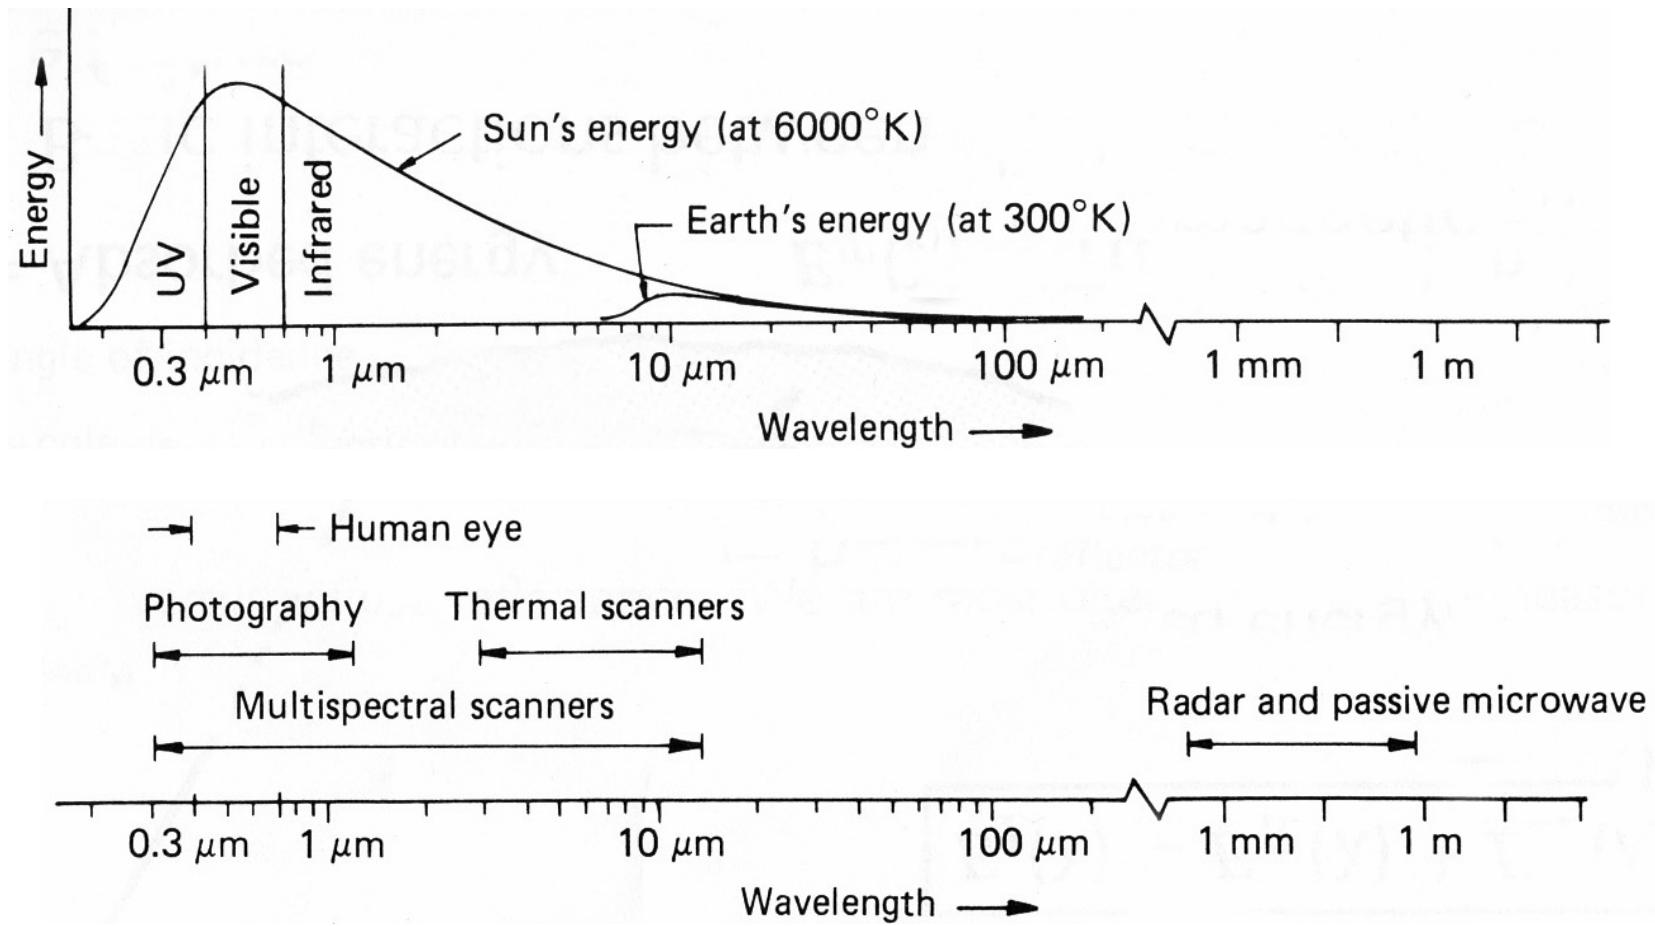

Satellite remote sensing of the Earth-atmosphere

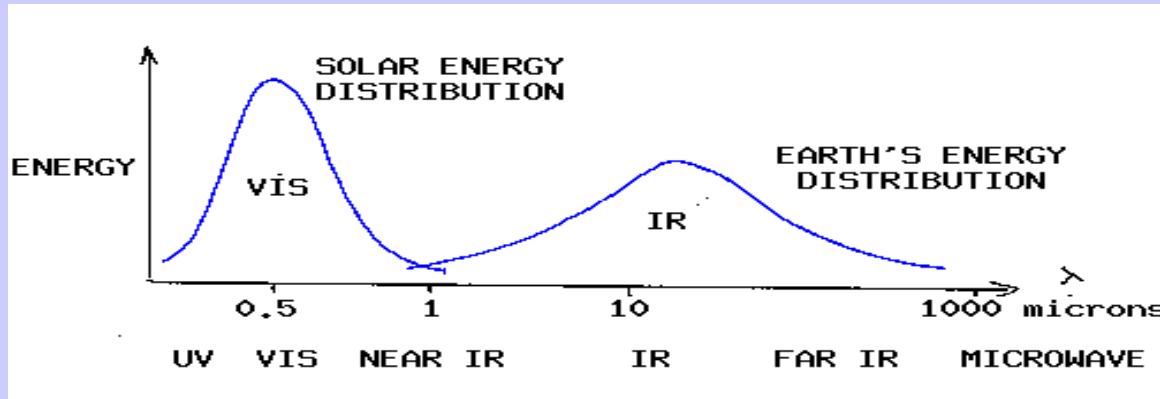

Observations depend on

- telescope characteristics (resolving power, diffraction)
- detector characteristics (signal to noise)
- communications bandwidth (bit depth)
- spectral intervals (window, absorption band)
- time of day (daylight visible)
- atmospheric state (T, Q, clouds)
- earth surface (Ts, vegetation cover)

Spectral Characteristics of Energy Sources and Sensing Systems

Solar (visible) and Earth emitted (infrared) energy

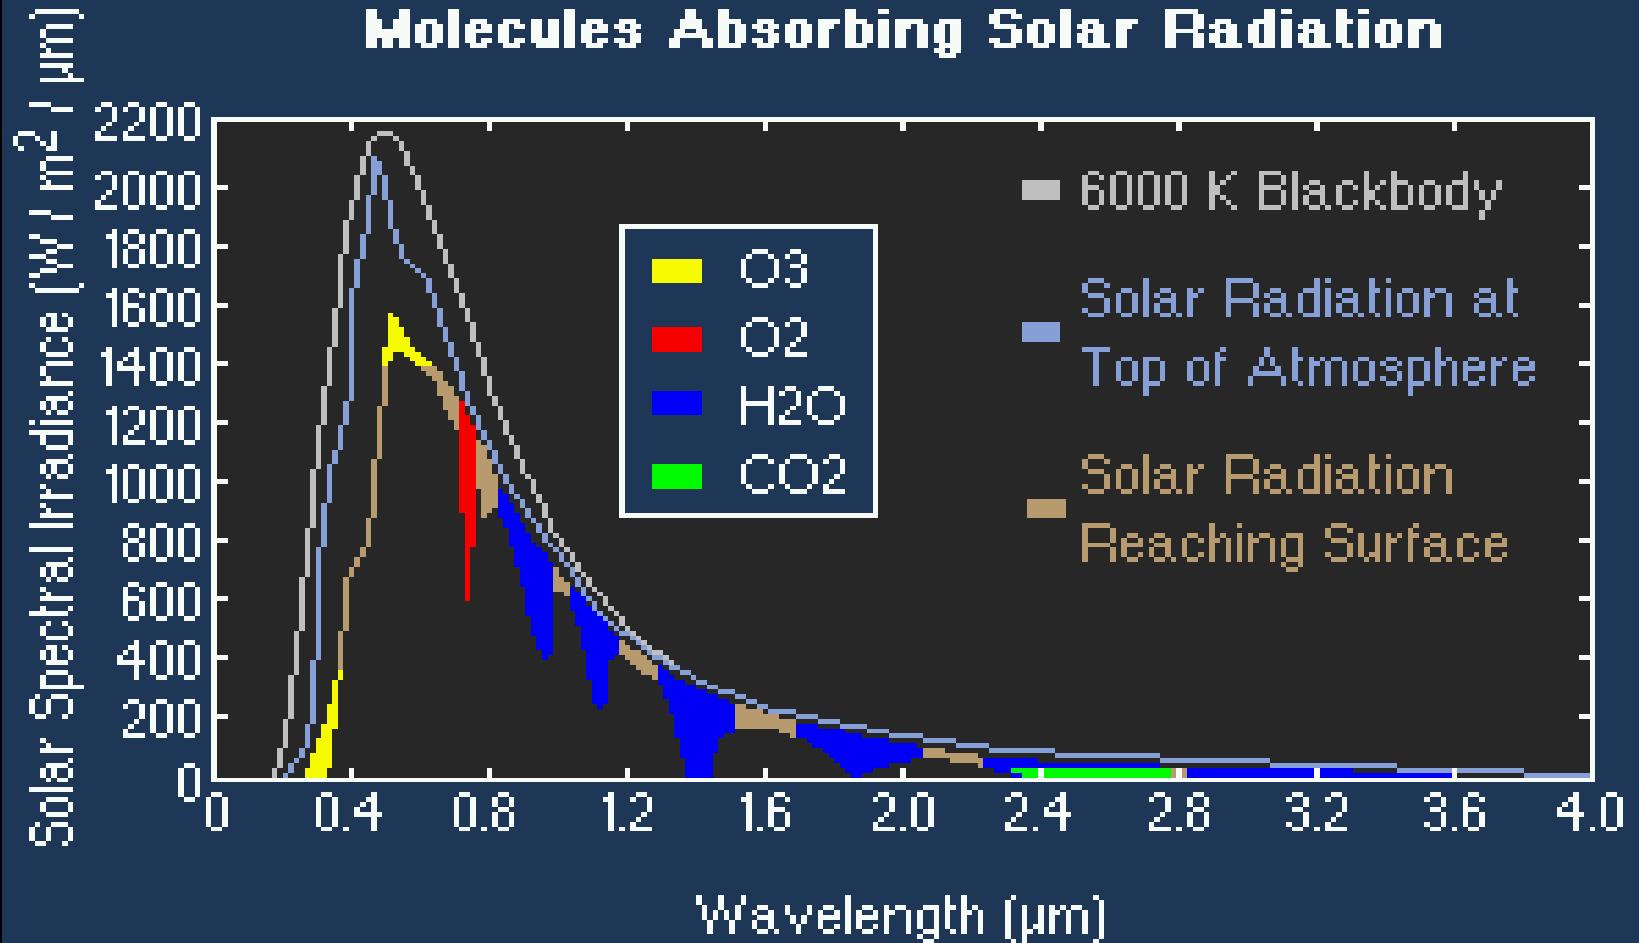

Incoming solar radiation (mostly visible) drives the earth-atmosphere (which emits infrared).

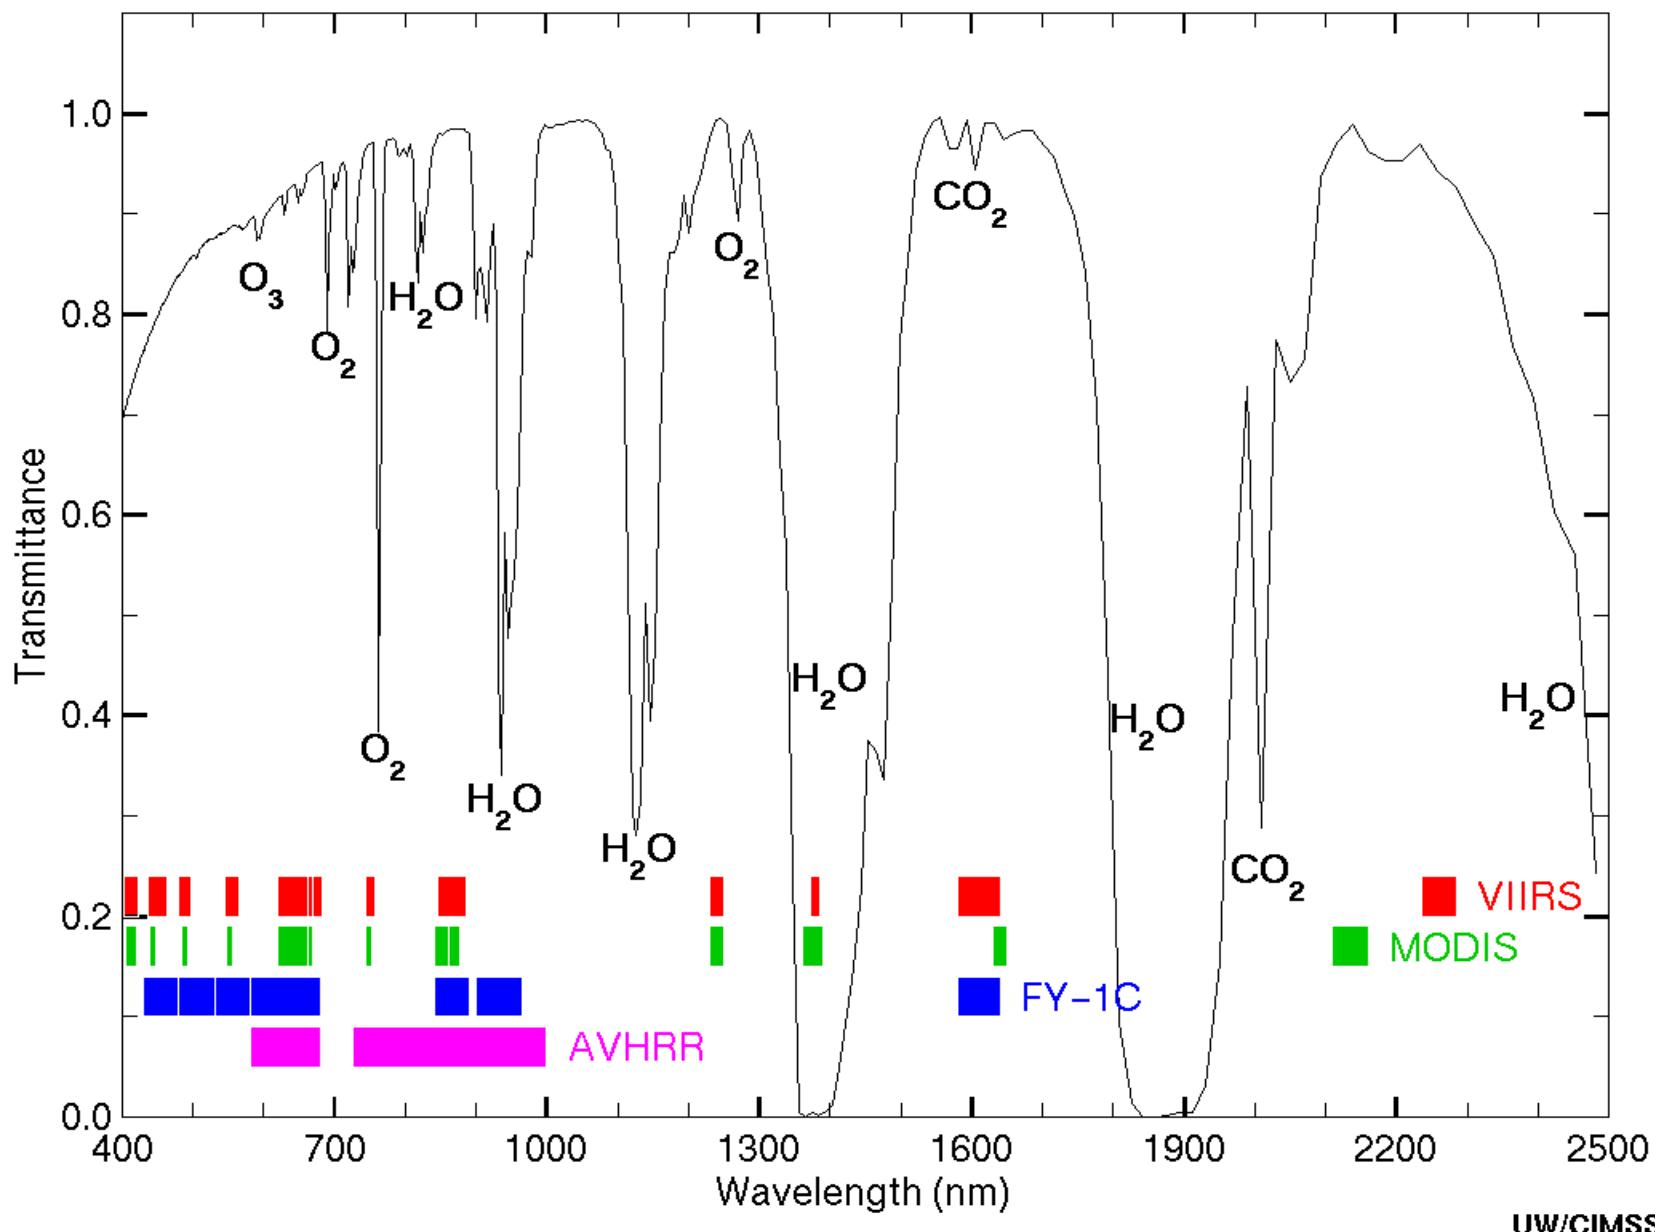

Over the annual cycle, the incoming solar energy that makes it to the earth surface (about 50 %) is balanced by the outgoing thermal infrared energy emitted through the atmosphere.

The atmosphere transmits, absorbs (by H₂O, O₂, O₃, dust) reflects (by clouds), and scatters (by aerosols) incoming visible; the earth surface absorbs and reflects the transmitted visible. Atmospheric H₂O, CO₂, and O₃ selectively transmit or absorb the outgoing infrared radiation. The outgoing microwave is primarily affected by H₂O and O₂.

Solar Spectrum

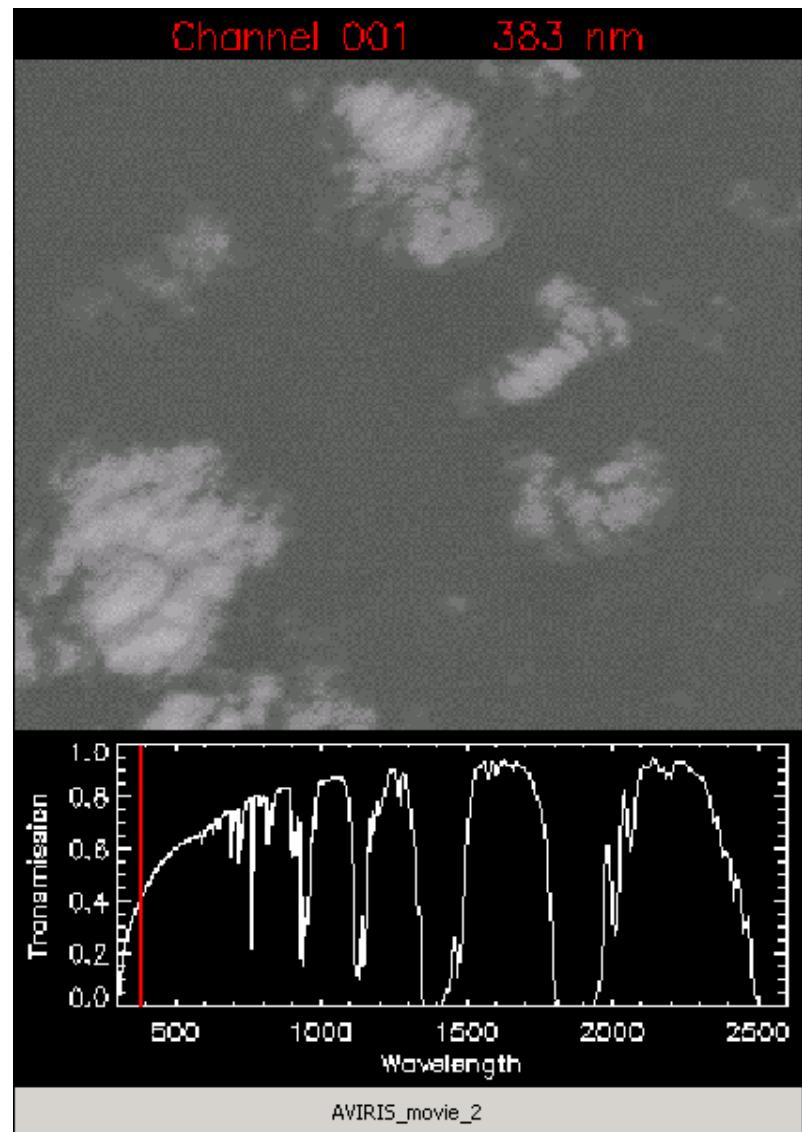

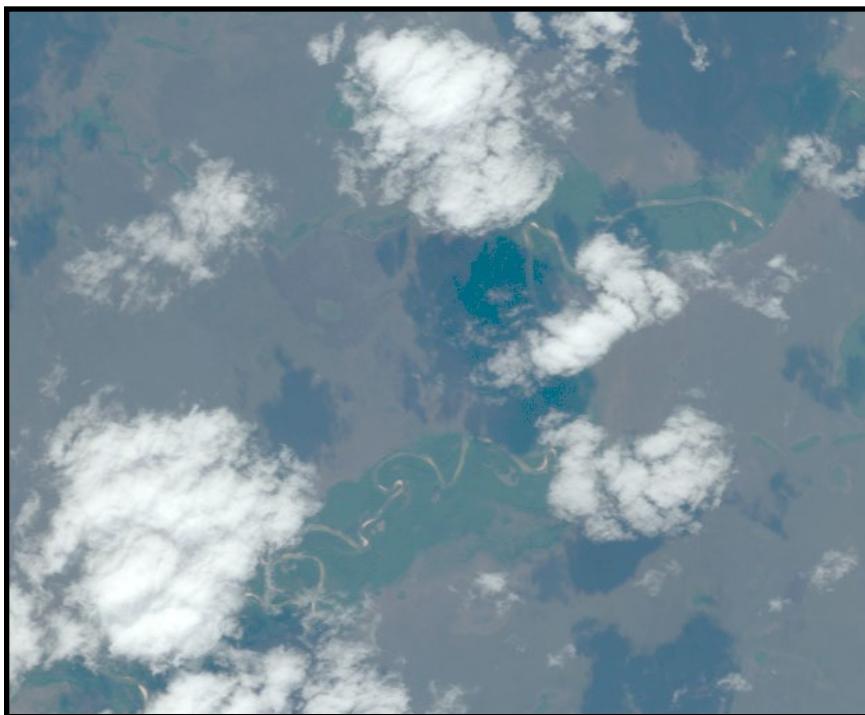

VIIRS, MODIS, FY-1C, AVHRR

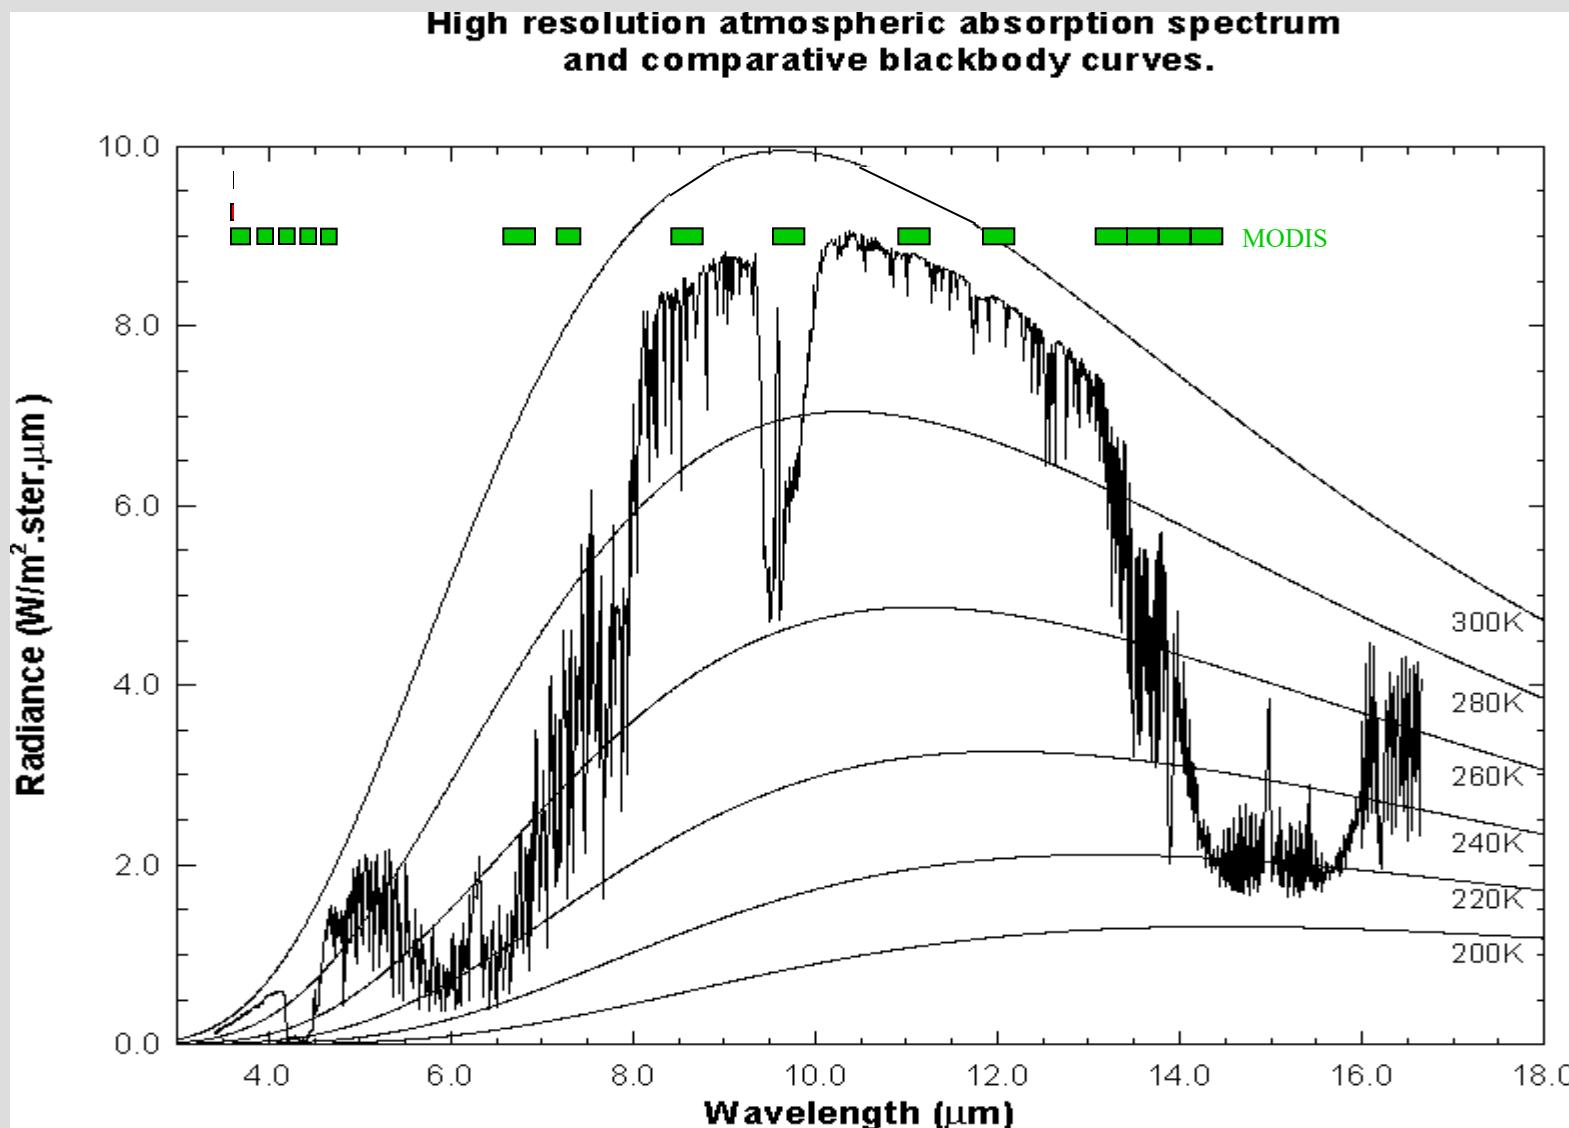

AVIRIS Movie #2

AVIRIS Image - Porto Nacional, Brazil

Radiative Transfer through the Atmosphere

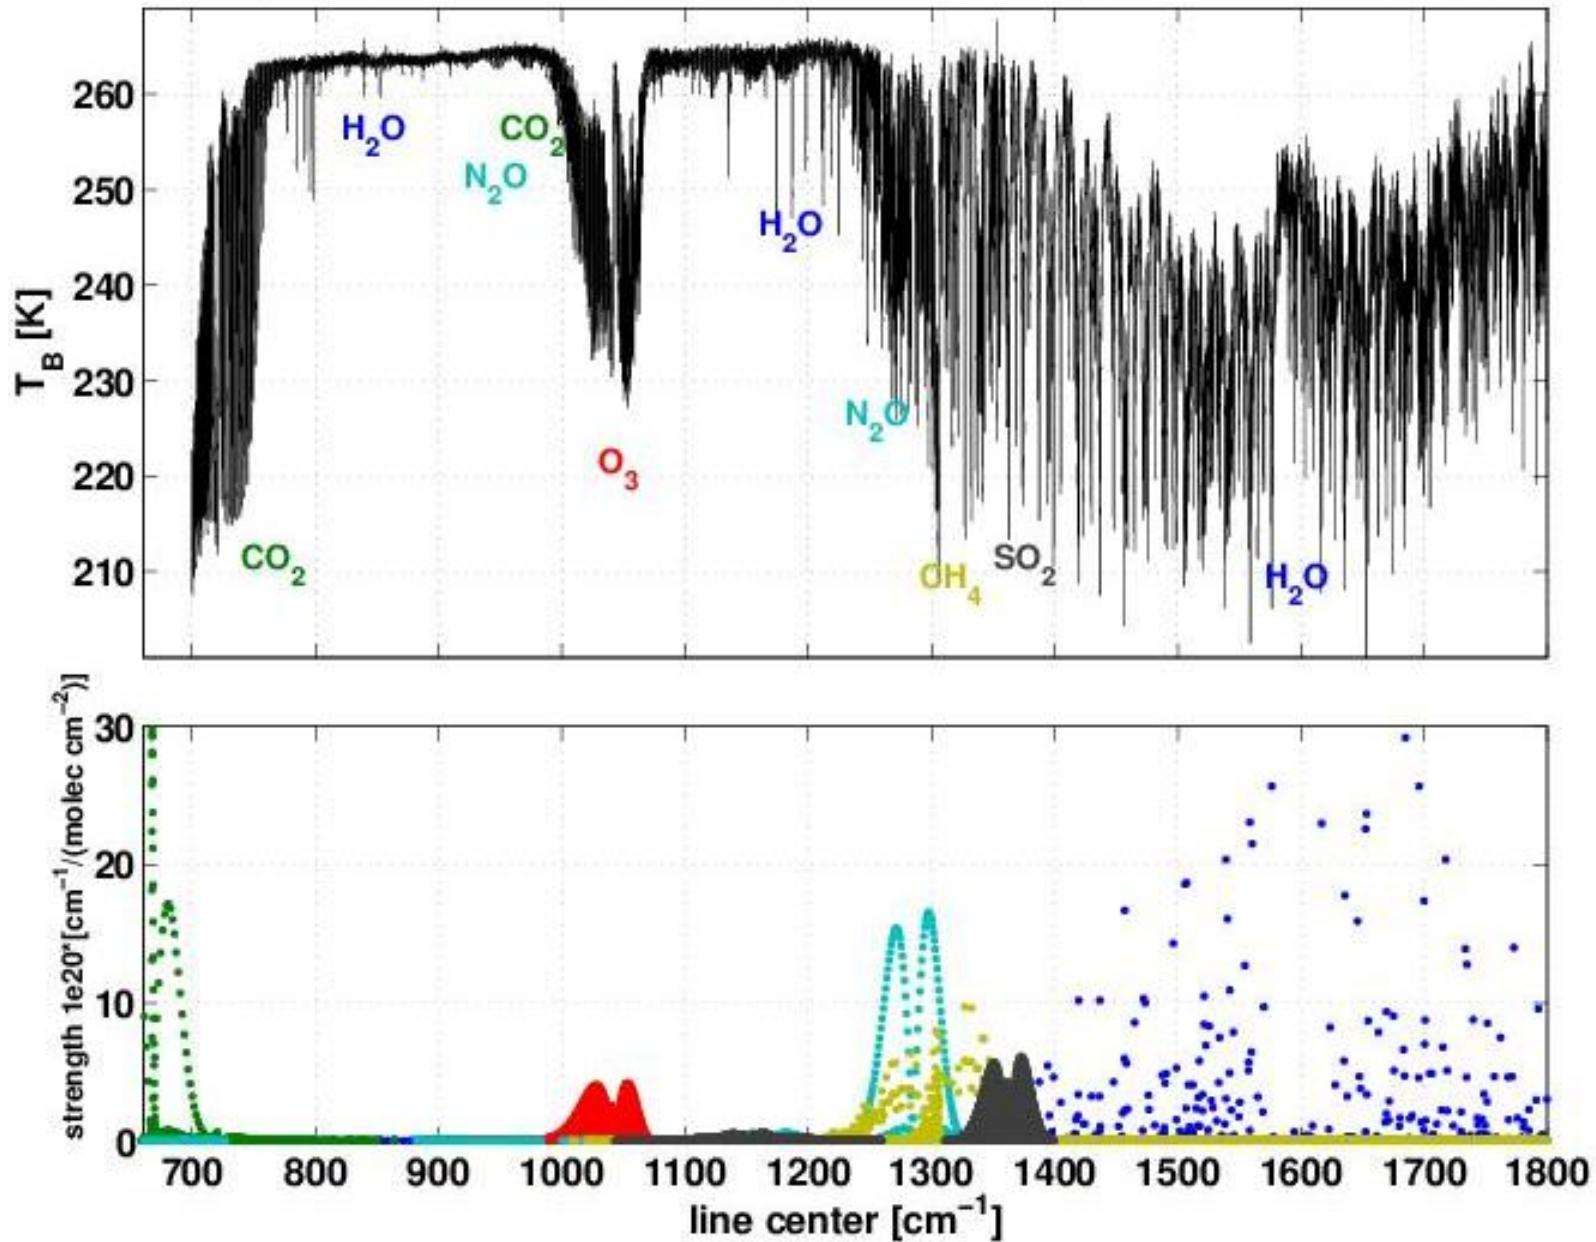

line broadening with pressure helps to explain weighting functions

AIRS radiance changes (in deg K) to atm & sfc changes

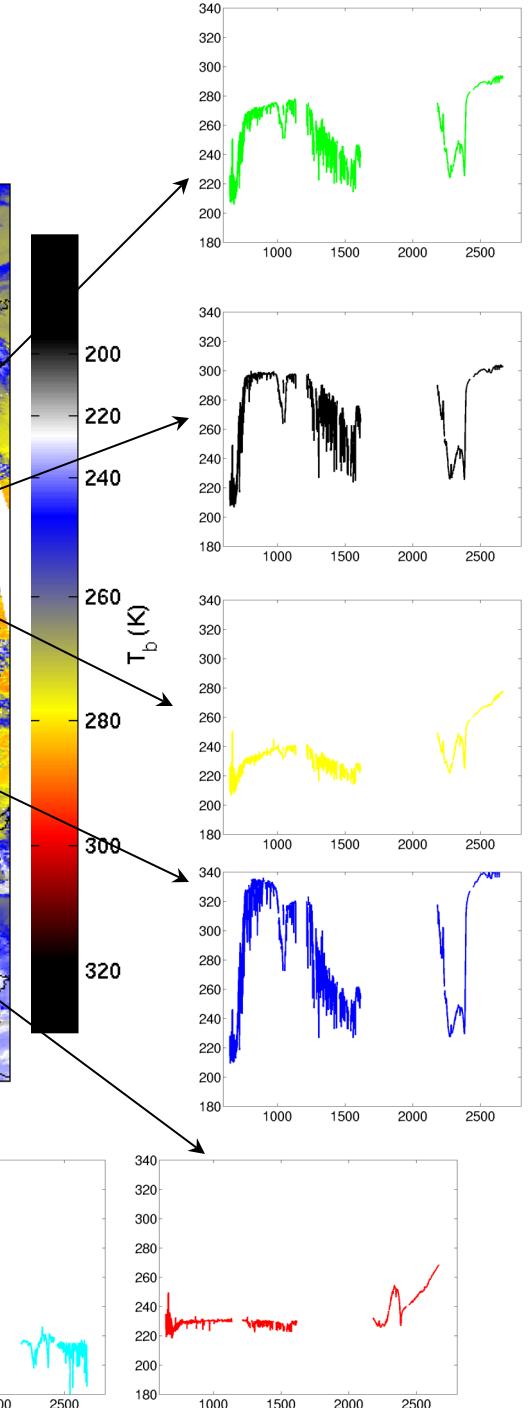

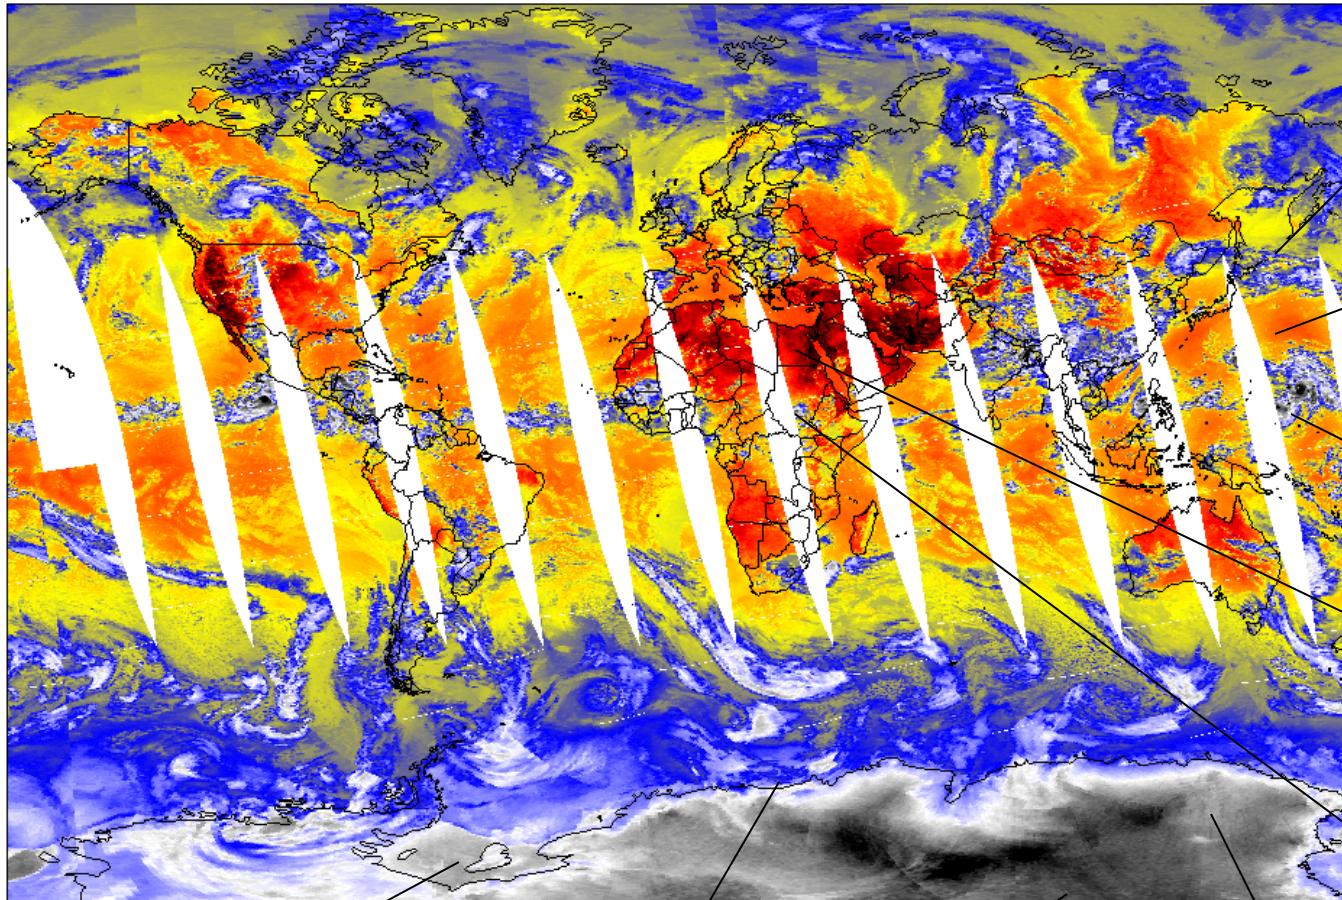

IMG spectrum (WINCE, 970128 over Nebraska) and HITRAN database

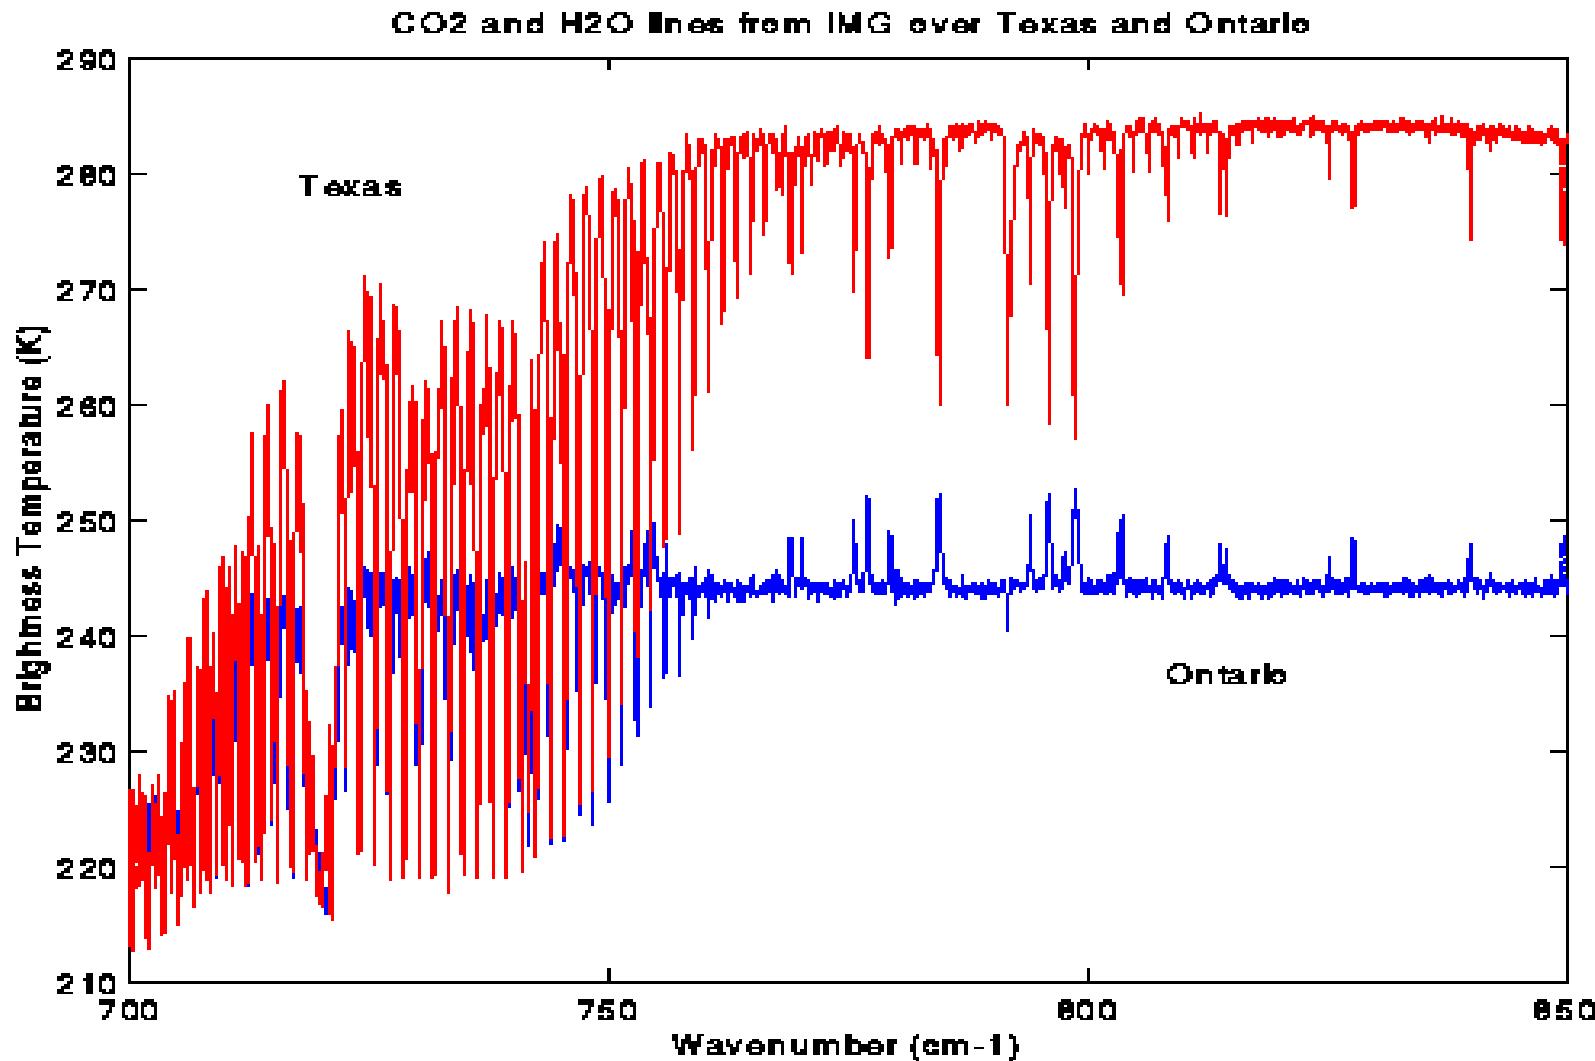

AIRS Spectra from around the Globe

20-July-2002 Ascending LW_Window

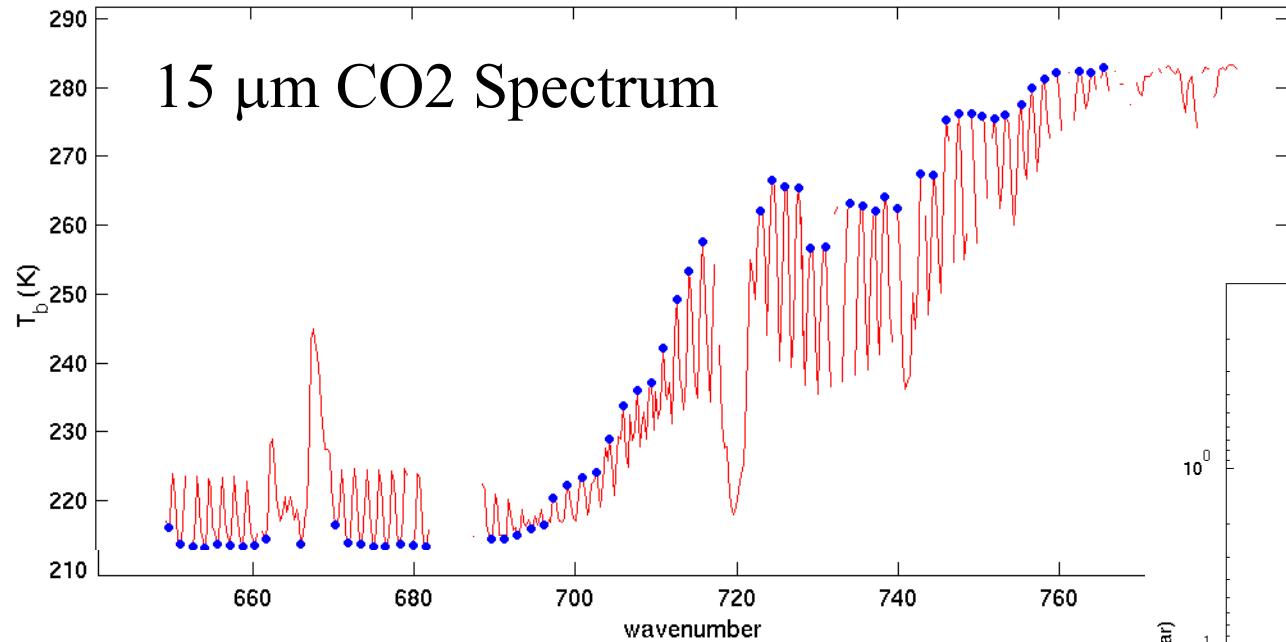

Sensitivity of High Spectral Resolution to Boundary Layer Inversions and Surface/atmospheric Temperature differences

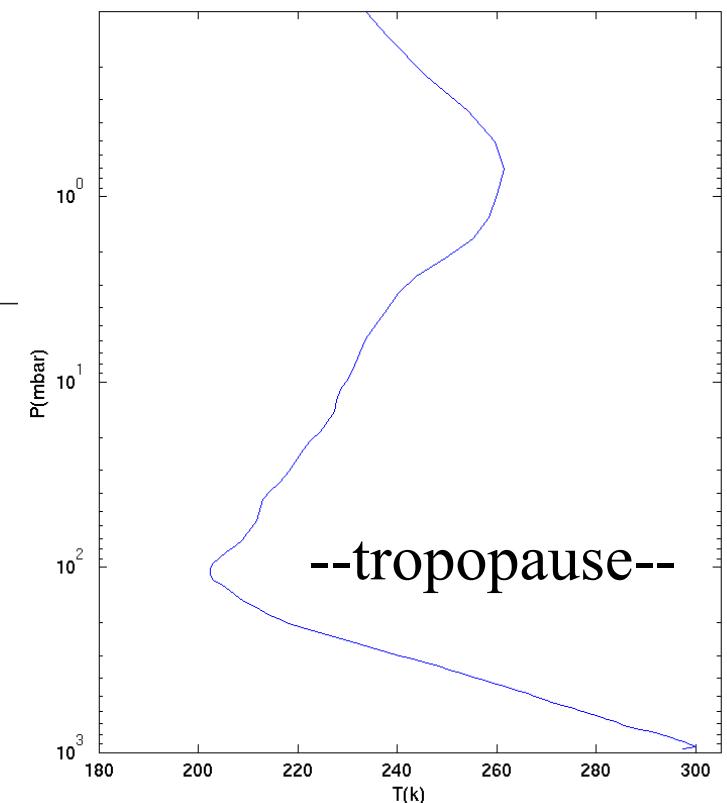

(from IMG Data, October, December 1996)

Twisted Ribbon formed by CO₂ spectrum: Tropopause inversion causes On-line & off-line patterns to cross

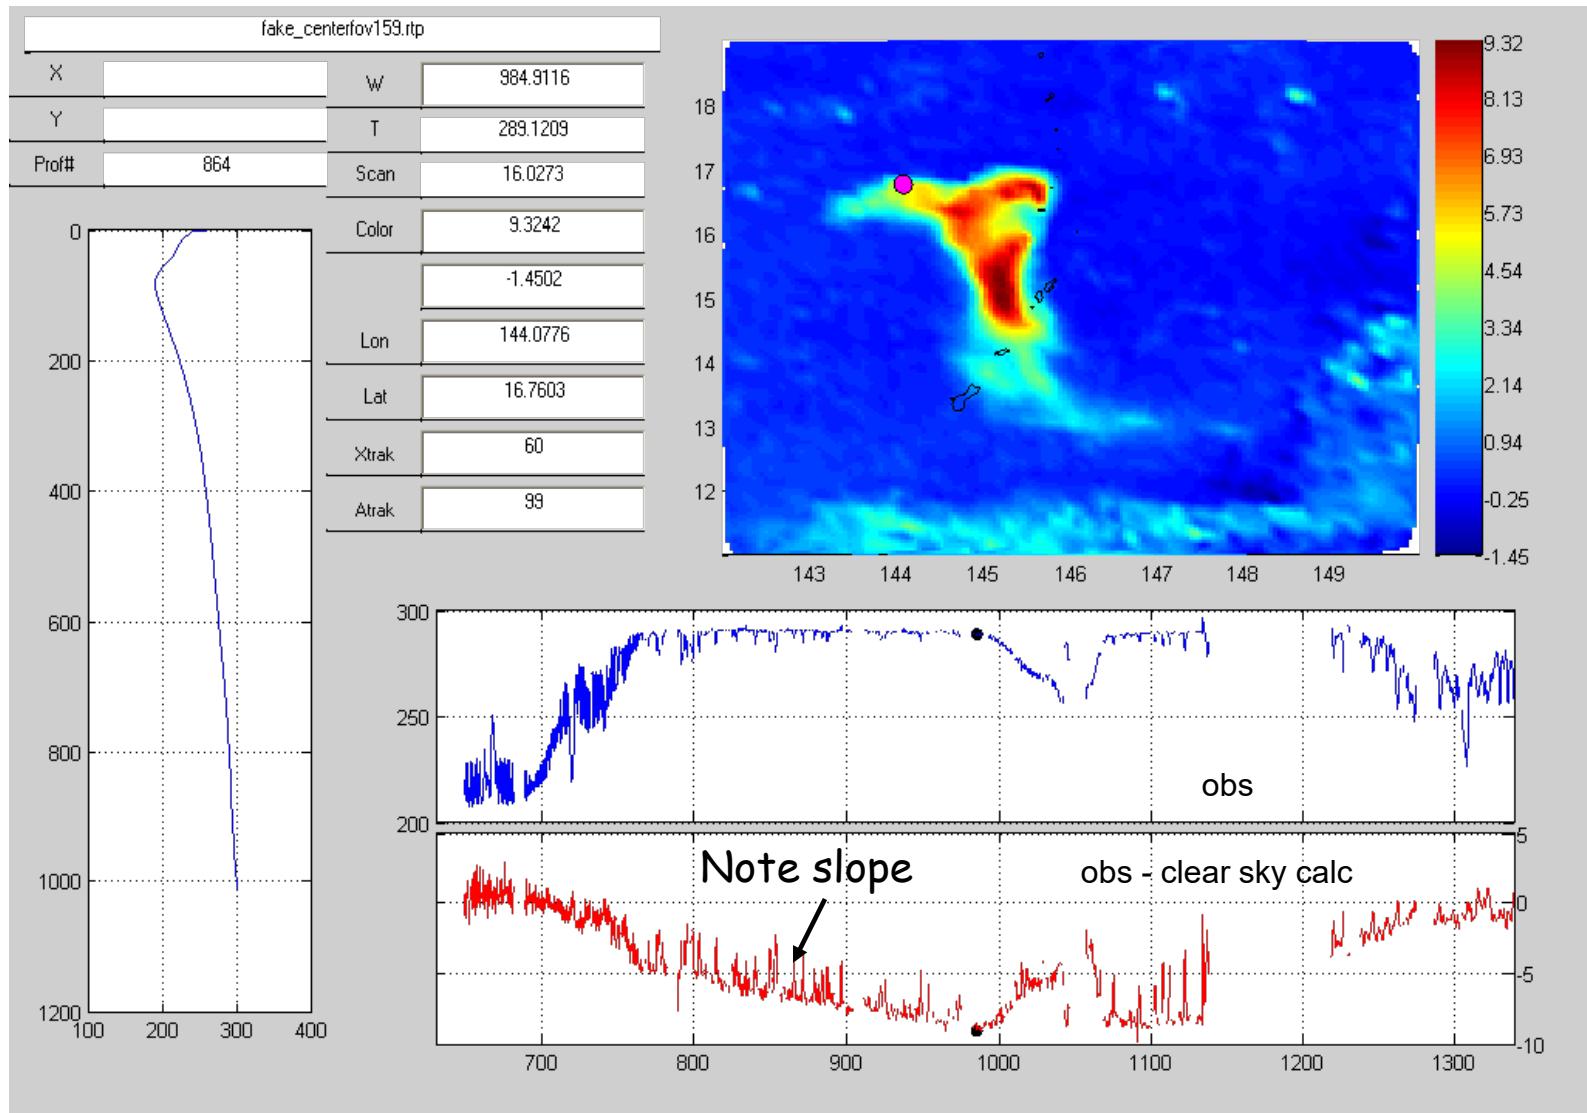

Blue between-line T_b
warmer for tropospheric channels,
colder for stratospheric channels

Signature not available at low resolution

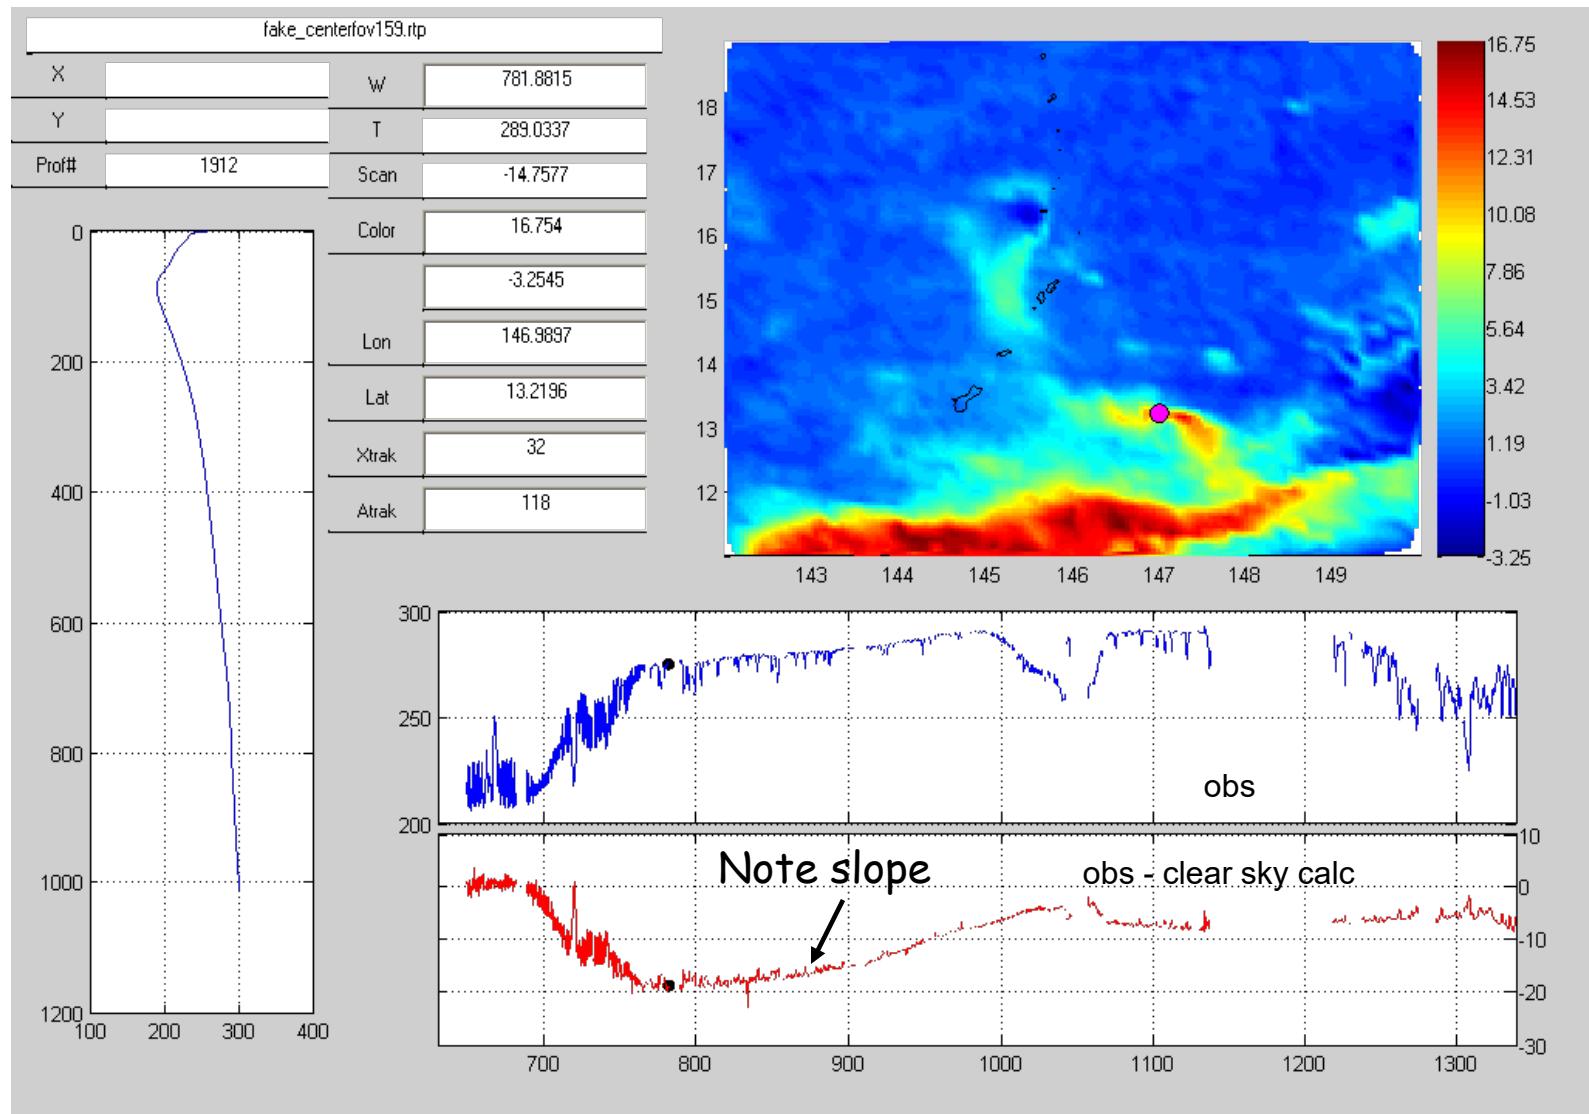

Silicate (ash cloud) signal at Anatahan, Mariana Is

Image is ECMWF bias difference of $1227\text{ cm}^{-1} - 984\text{ cm}^{-1}$ (double difference)

Cirrus signal at Anatahan

Image is ECMWF T_b bias difference of 1227 cm⁻¹ - 781 cm⁻¹ (double difference)

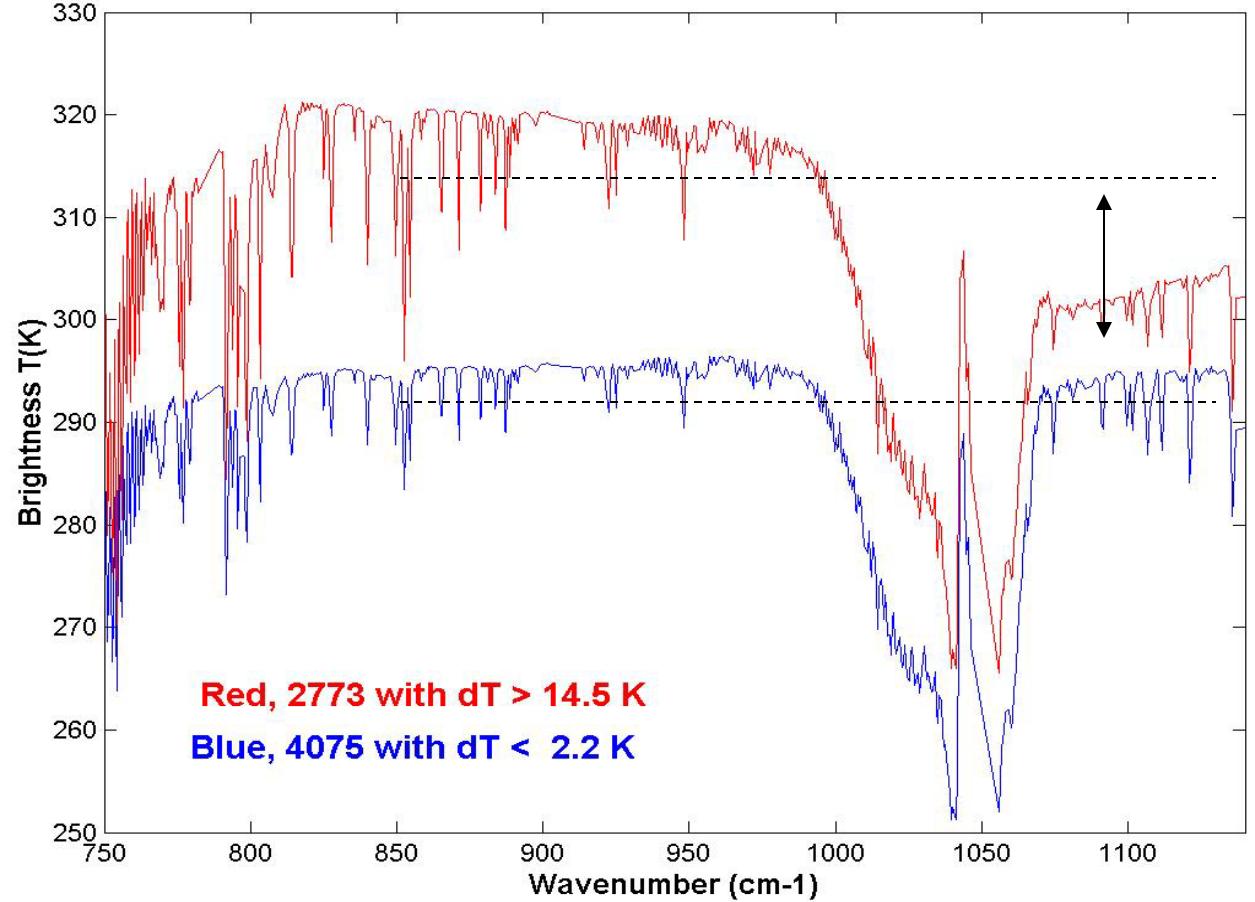

Inferreding surface properties with AIRS high spectral resolution data

Barren region detection if $T(1086 \text{ cm}^{-1}) < T(981 \text{ cm}^{-1})$

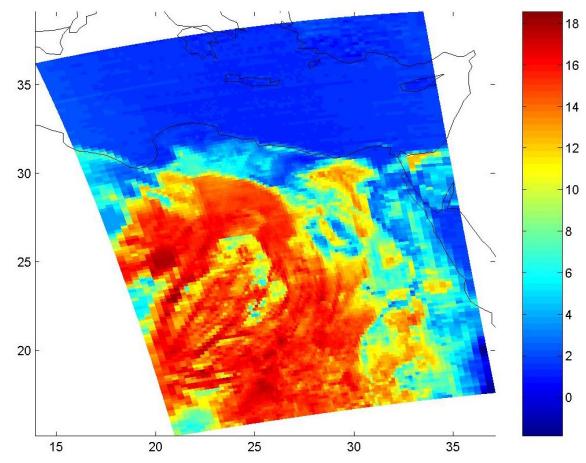

Barren vs Water/Vegetated

Means with $981-1086 \text{ cm}^{-1}$ Large (red) & Small (blue), g115

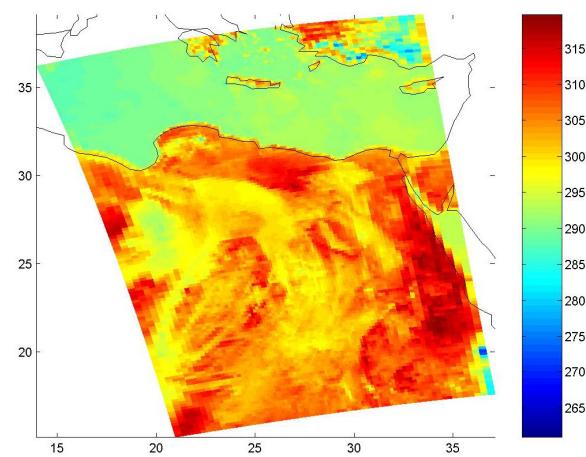

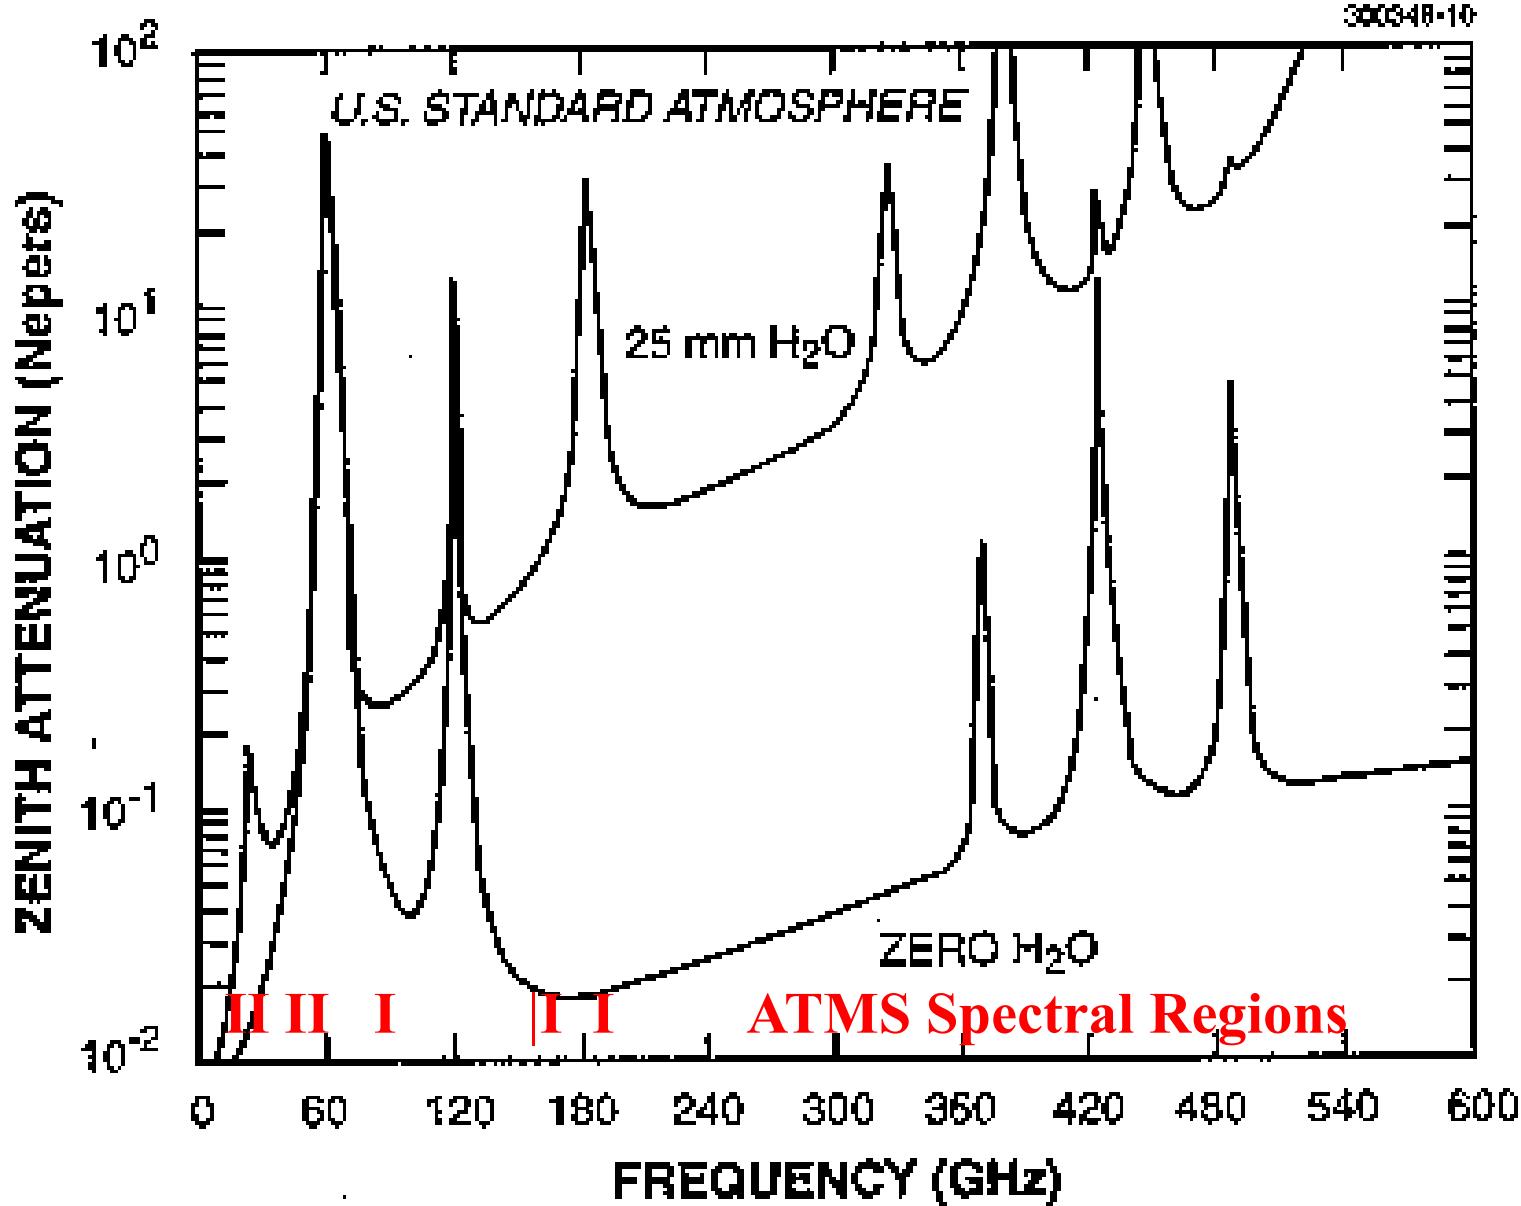

AIRS data from 14 June 2002

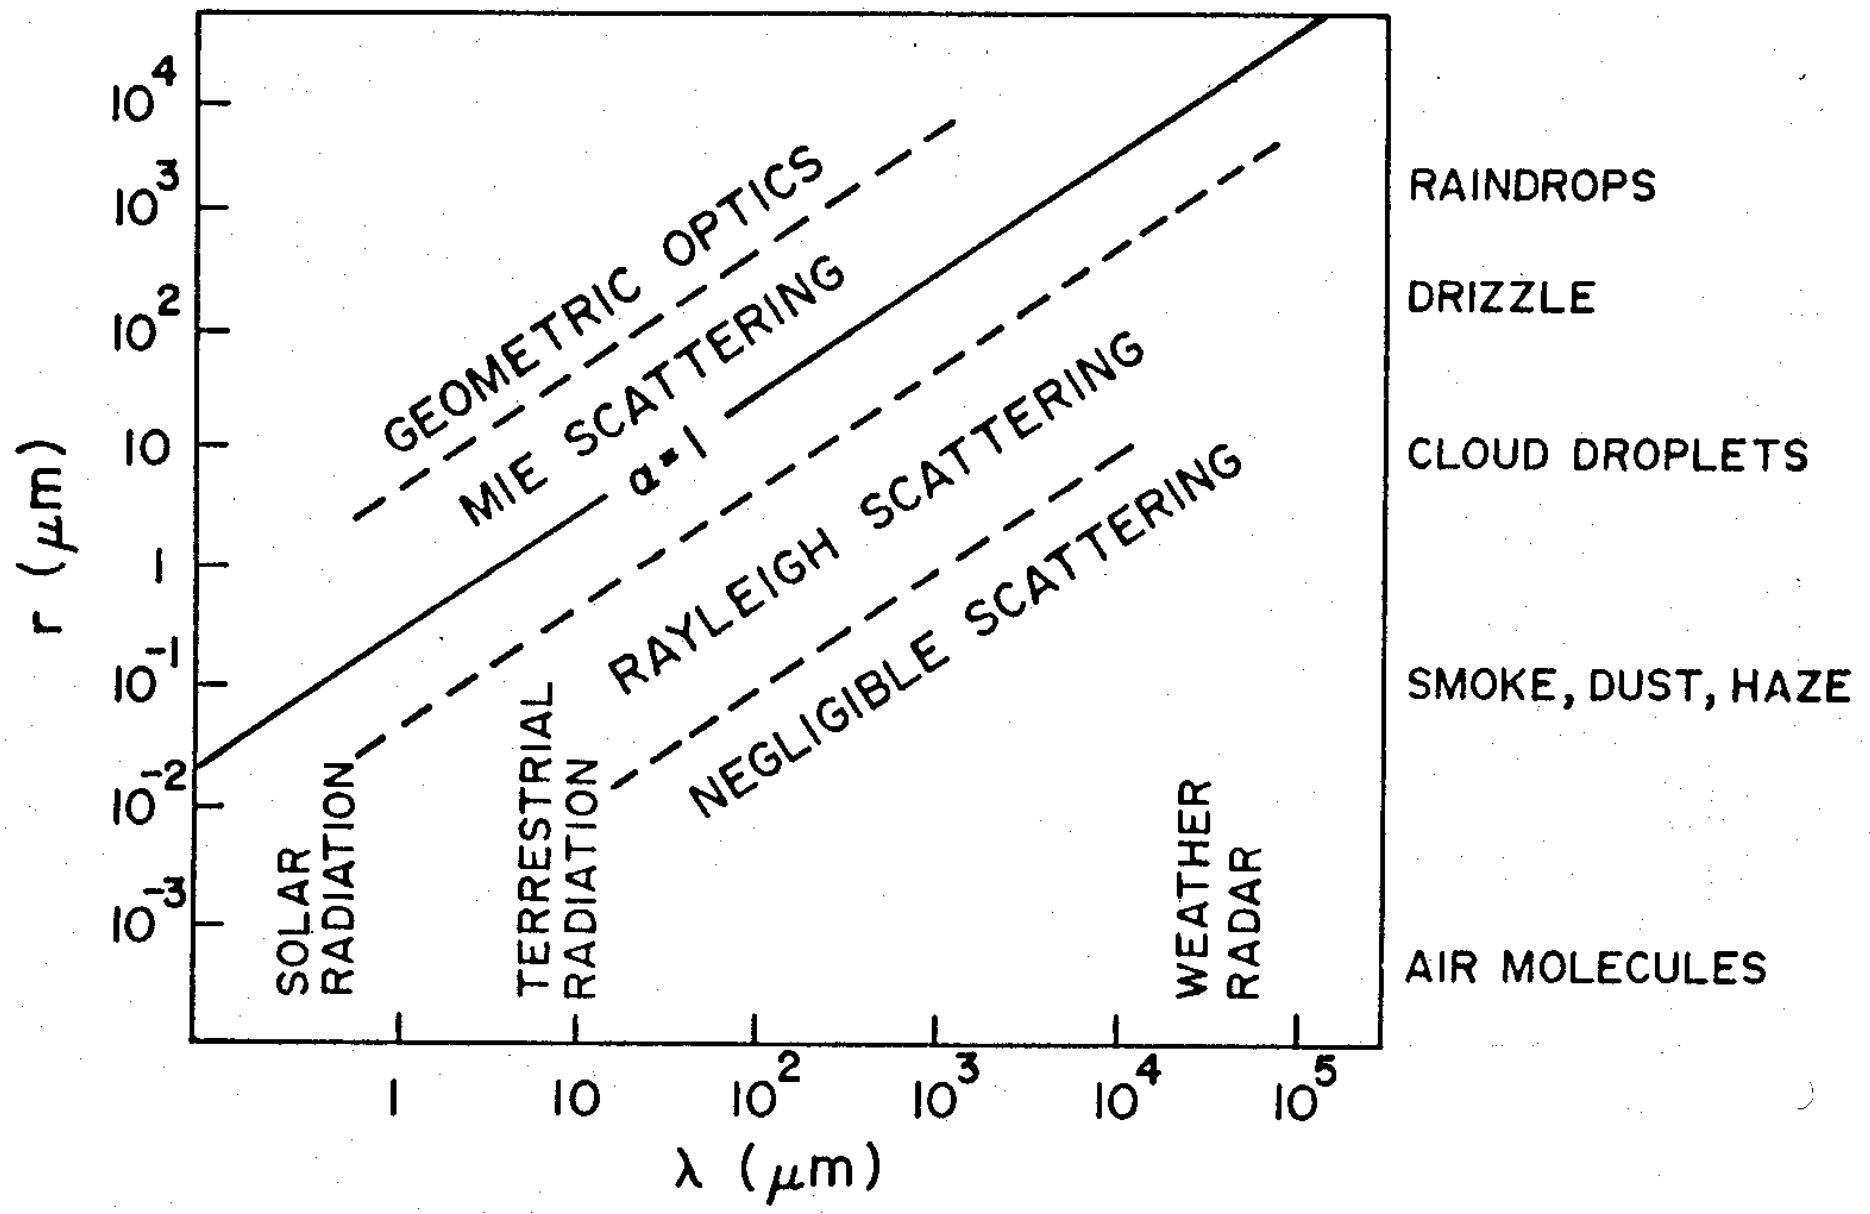

$T(981 \text{ cm}^{-1}) - T(1086 \text{ cm}^{-1})$

$T(1086 \text{ cm}^{-1})$

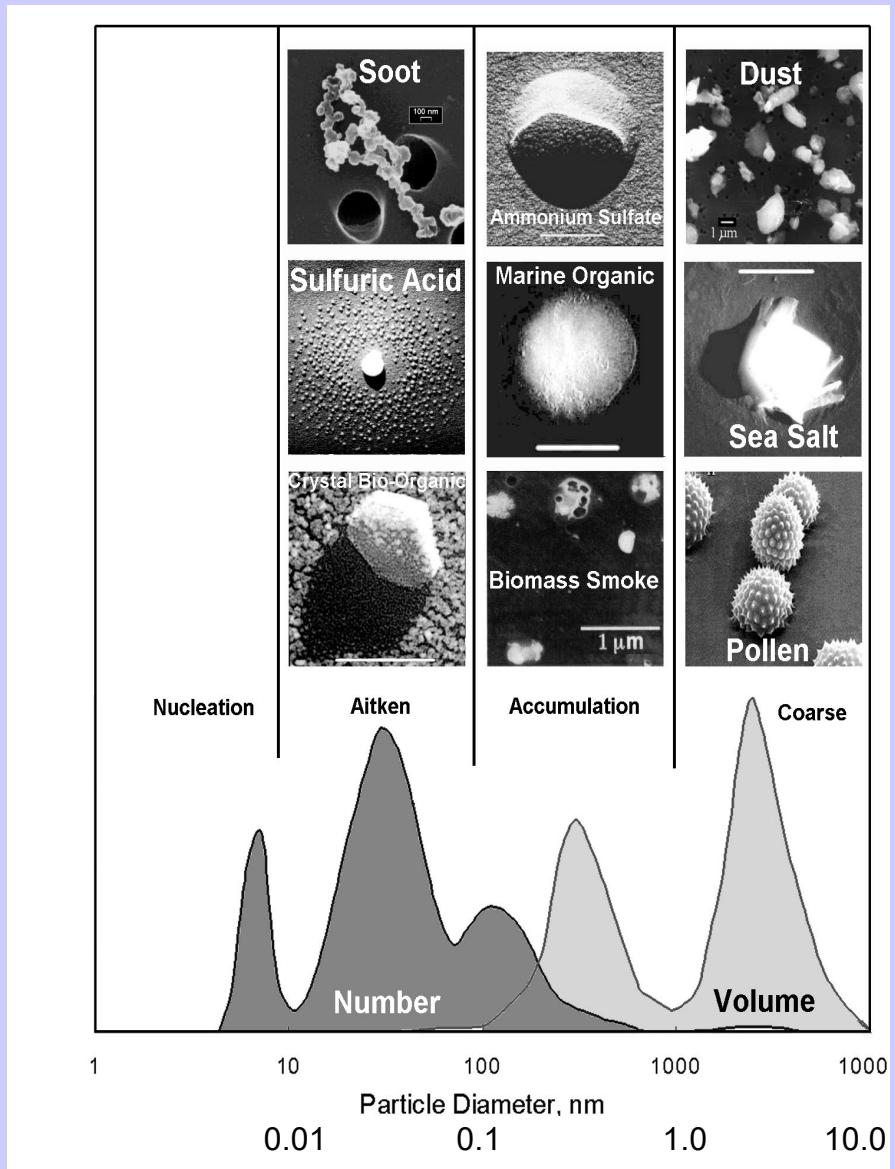

Aerosol Size Distribution

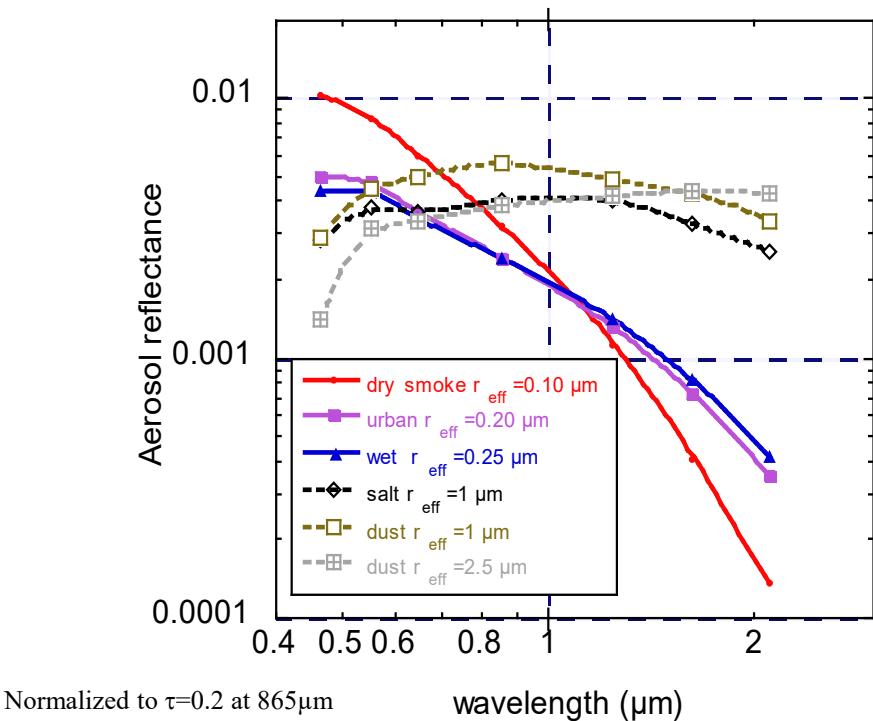

There are 3 modes :

- « **nucleation** »: radius is between 0.002 and 0.05 μm . They result from combustion processes, photo-chemical reactions, etc.
- « **accumulation** »: radius is between 0.05 μm and 0.5 μm . Coagulation processes.
- « **coarse** »: larger than 1 μm . From mechanical processes like aeolian erosion.

« fine » particles (nucleation and accumulation) result from anthropogenic activities, coarse particles come from natural processes.

Aerosols over Ocean

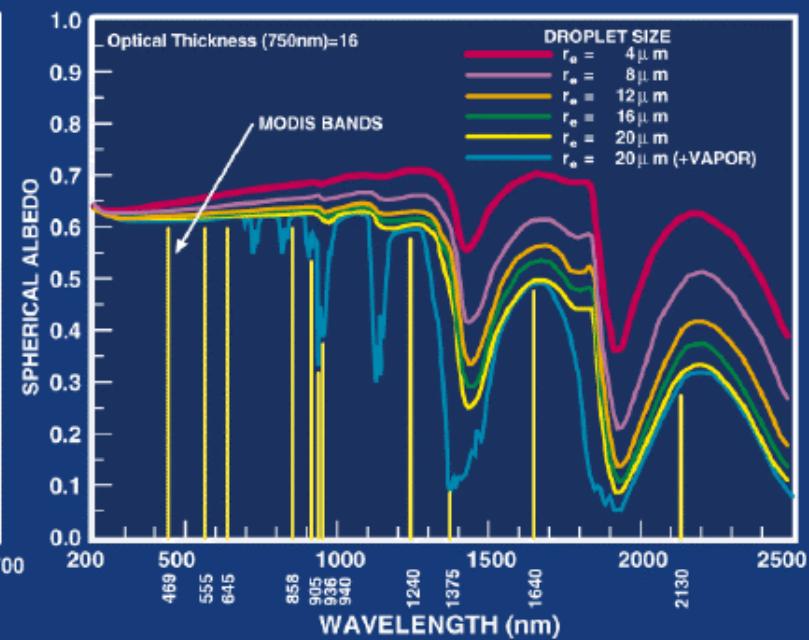

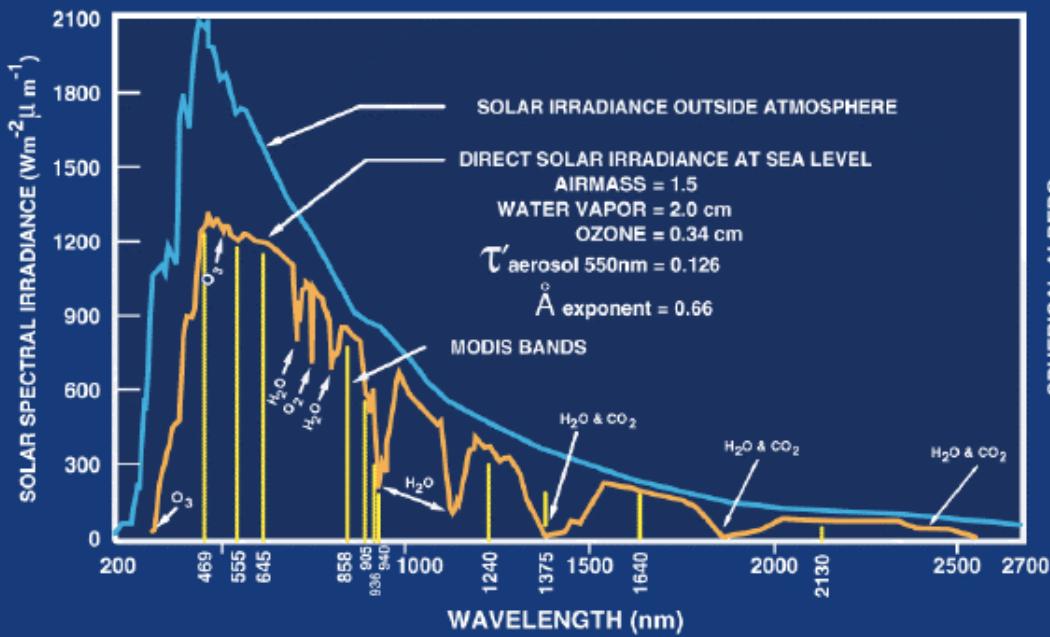

- Radiance data in 6 bands (550-2130nm).
- Spectral radiances (LUT) to derive the aerosol size distribution
- Two modes (accumulation 0.10-0.25 μm ; coarse 1.0-2.5 μm); ratio is a free parameter
- Radiance at $865\mu m$ to derive τ

Ocean products :

- The total Spectral Optical thickness
- The effective radius
- The optical thickness of small & large modes/ratio between the 2 modes

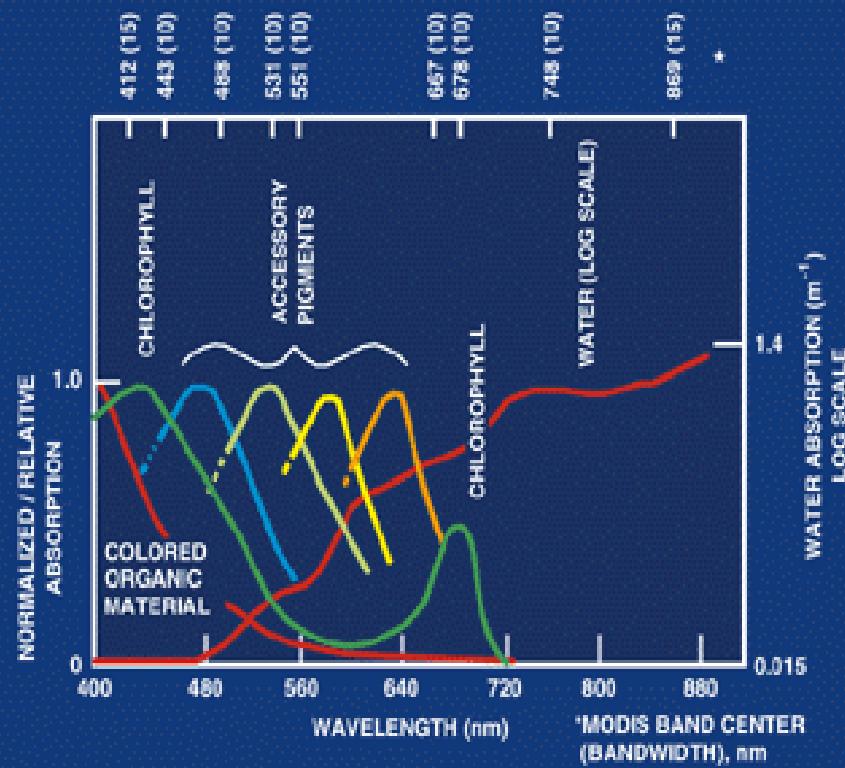

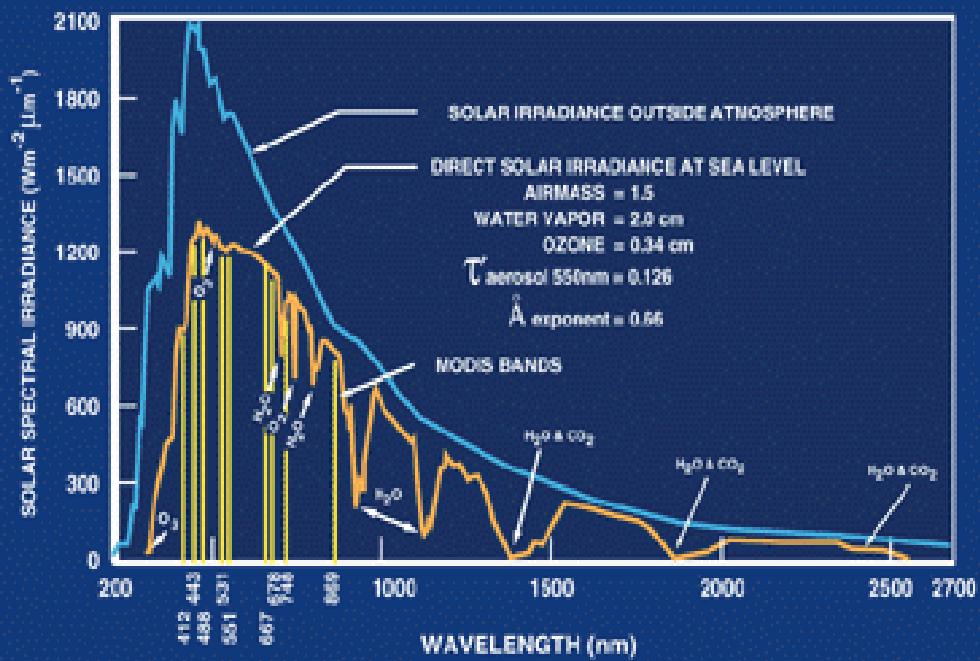

ATMOSPHERE-SOLAR RADIATION

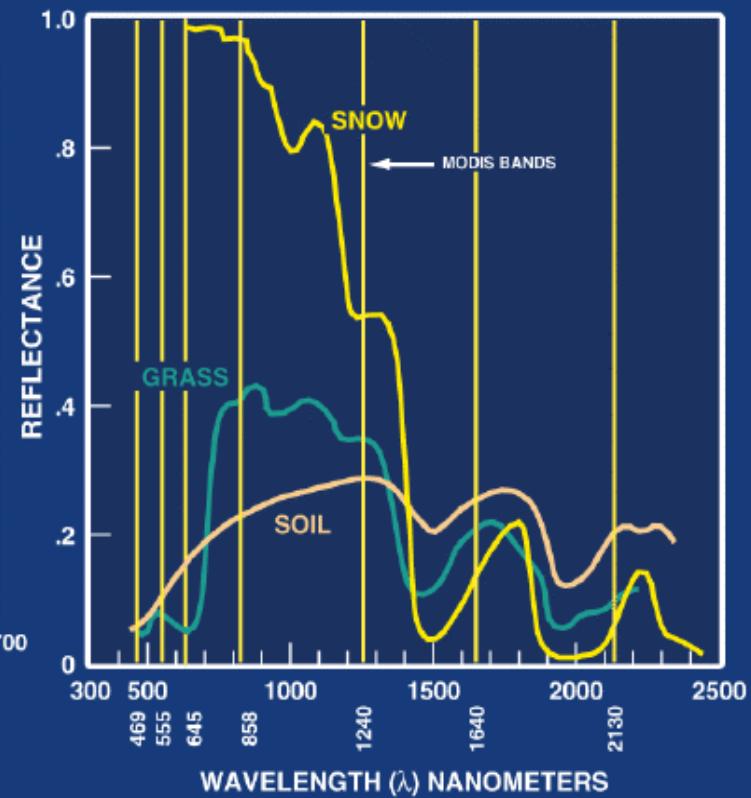

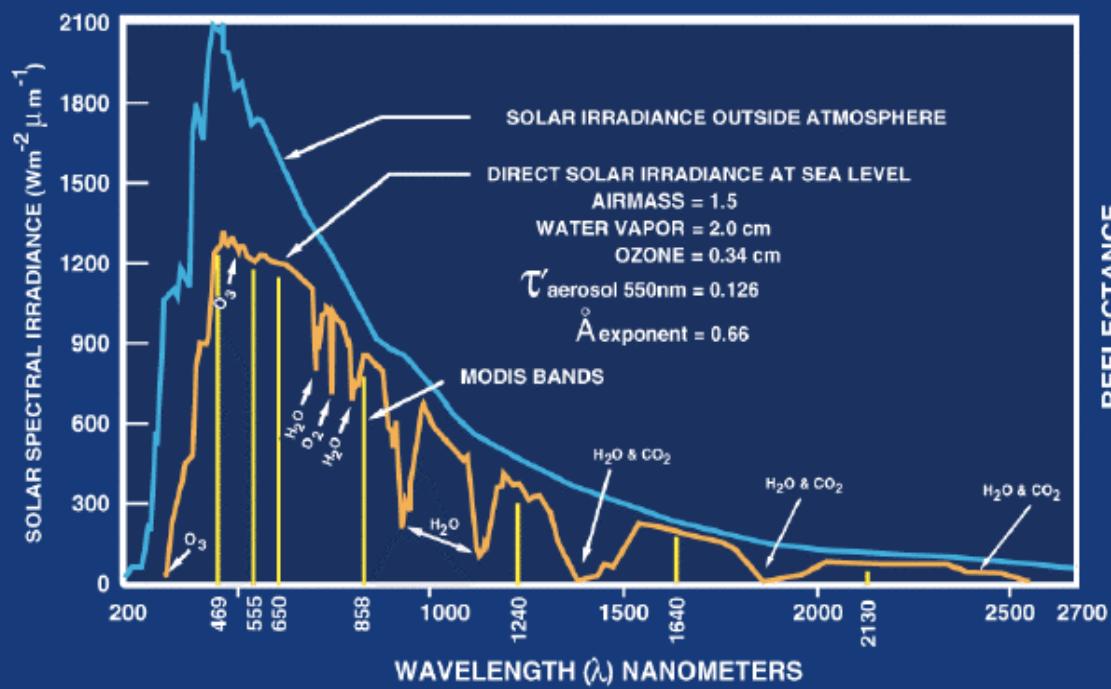

OCEAN-SOLAR RADIATION

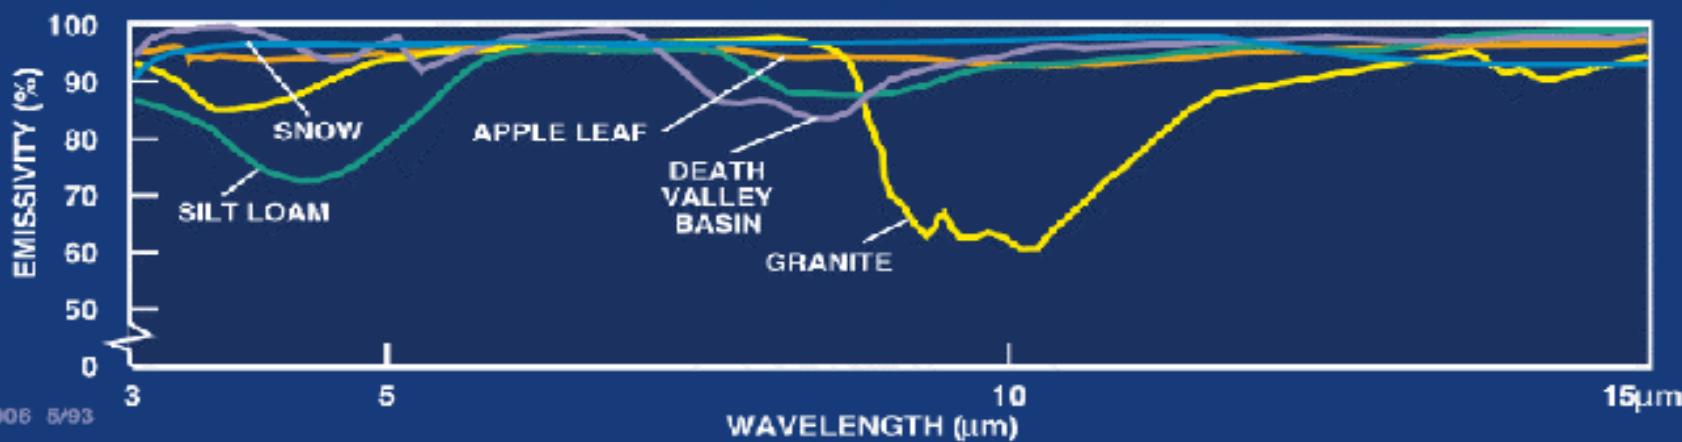

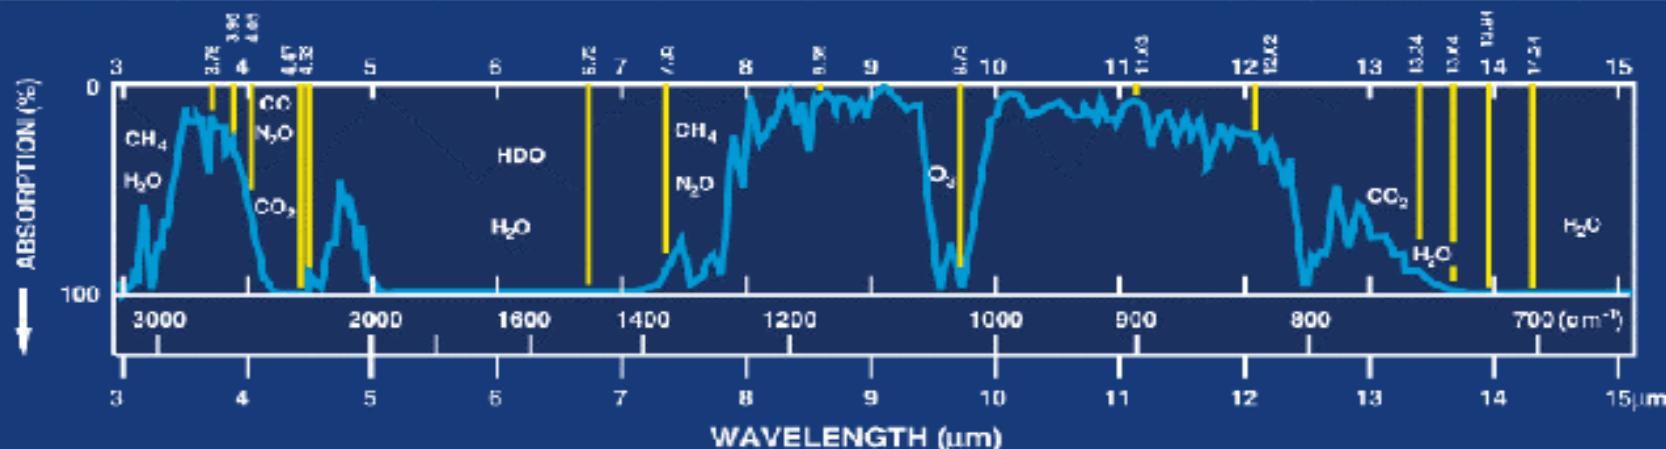

LAND-SOLAR RADIATION

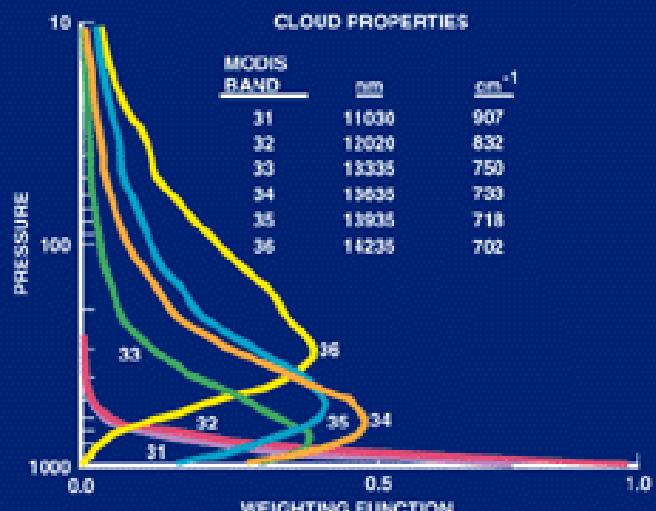

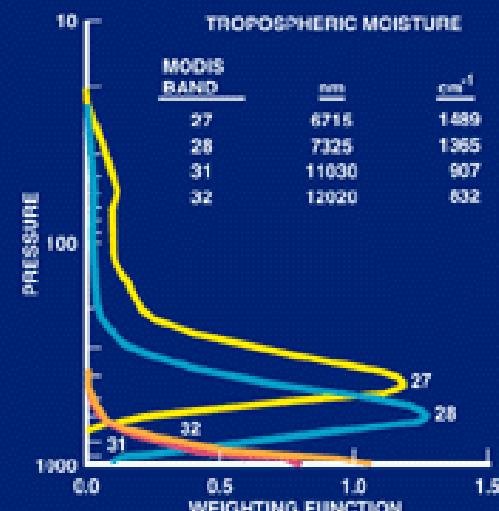

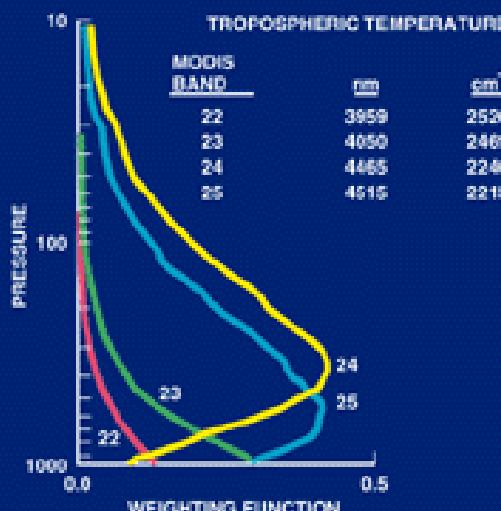

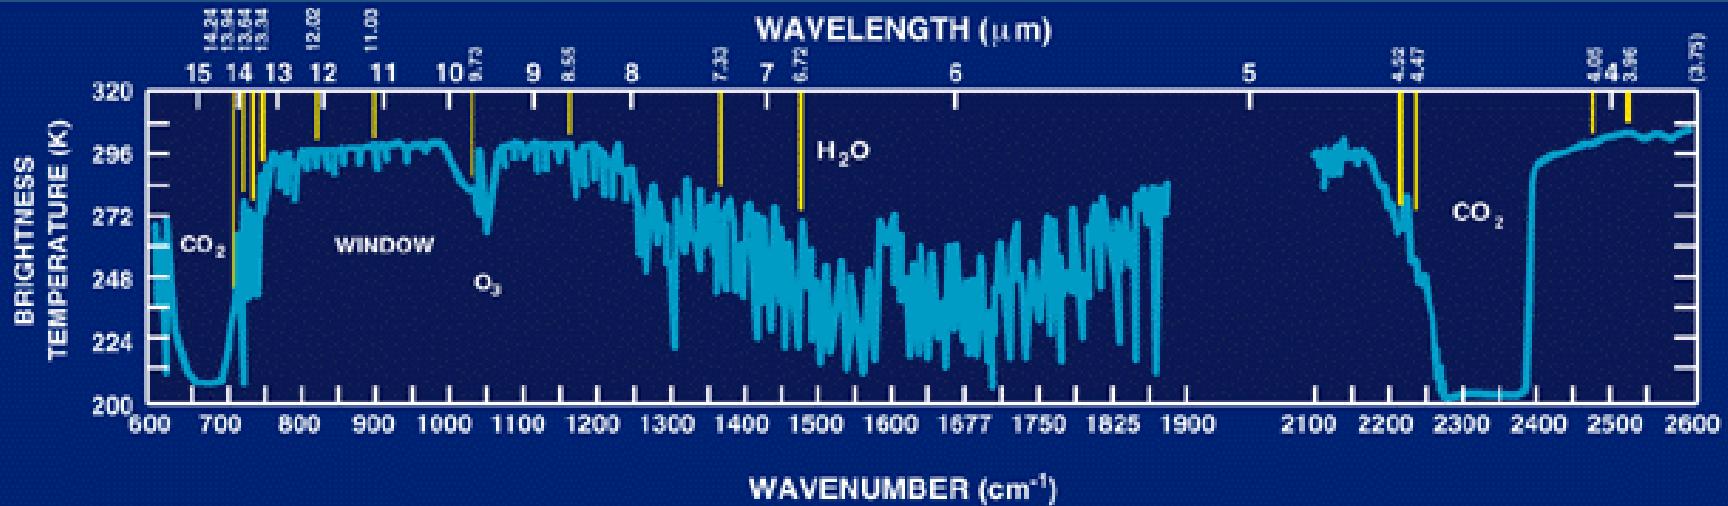

LAND - THERMAL RADIATION

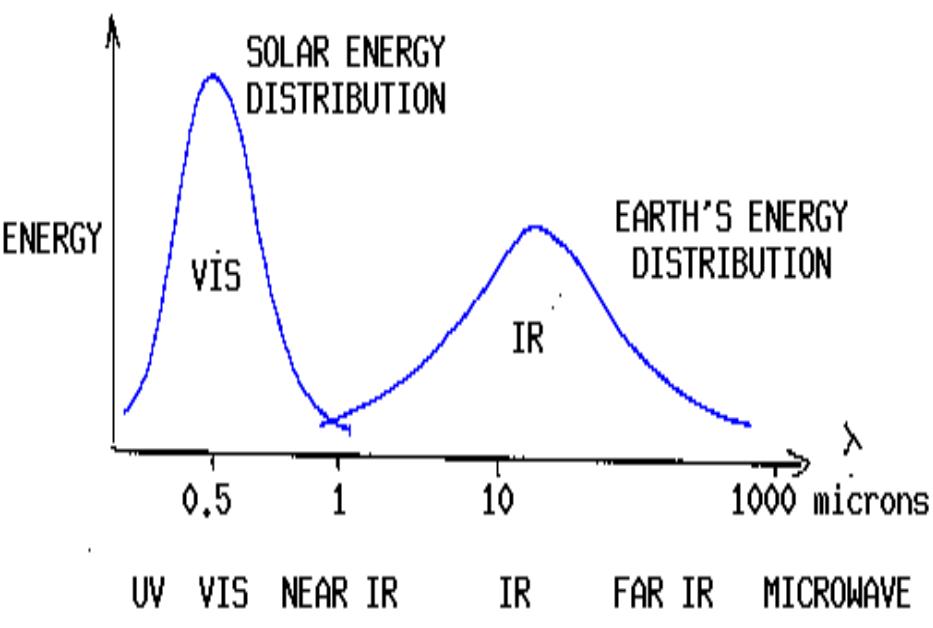

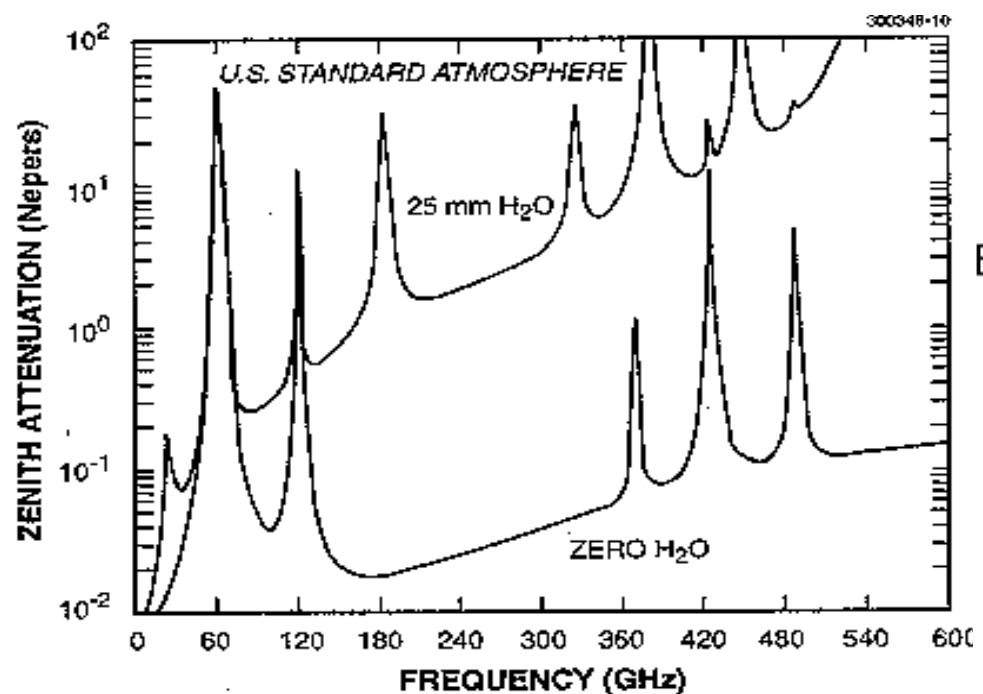

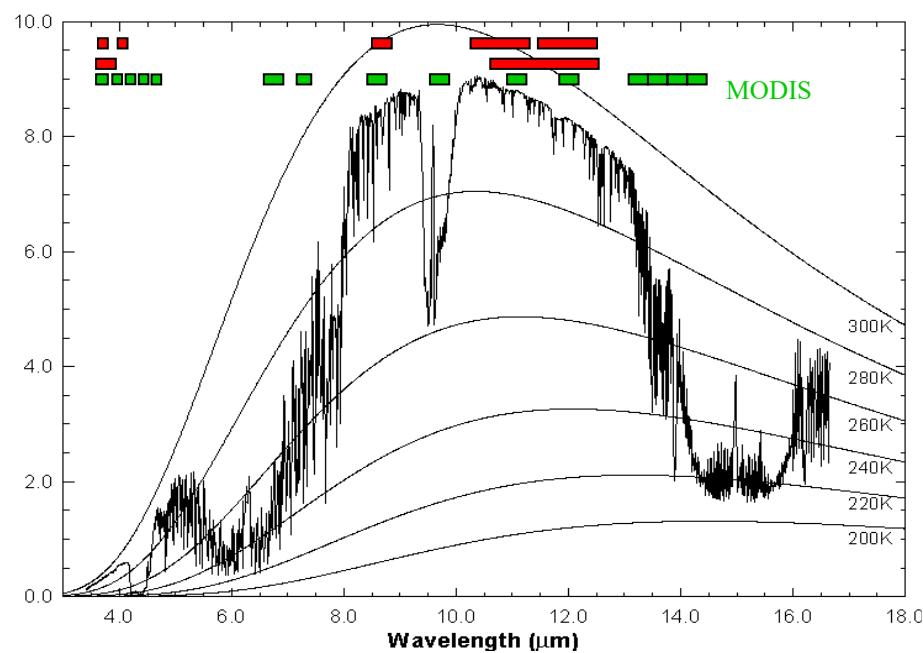

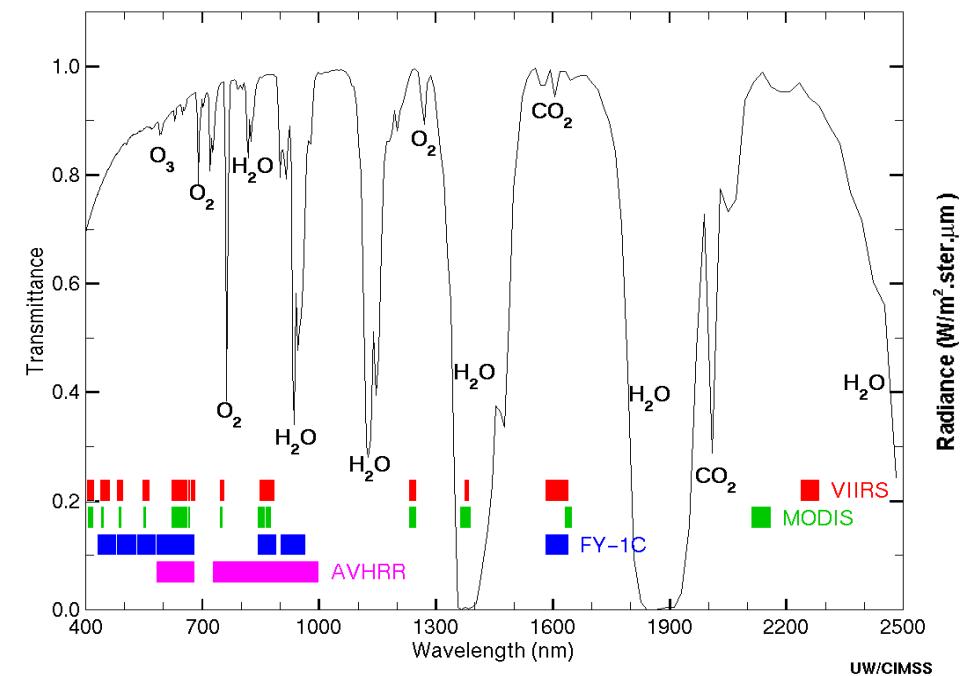

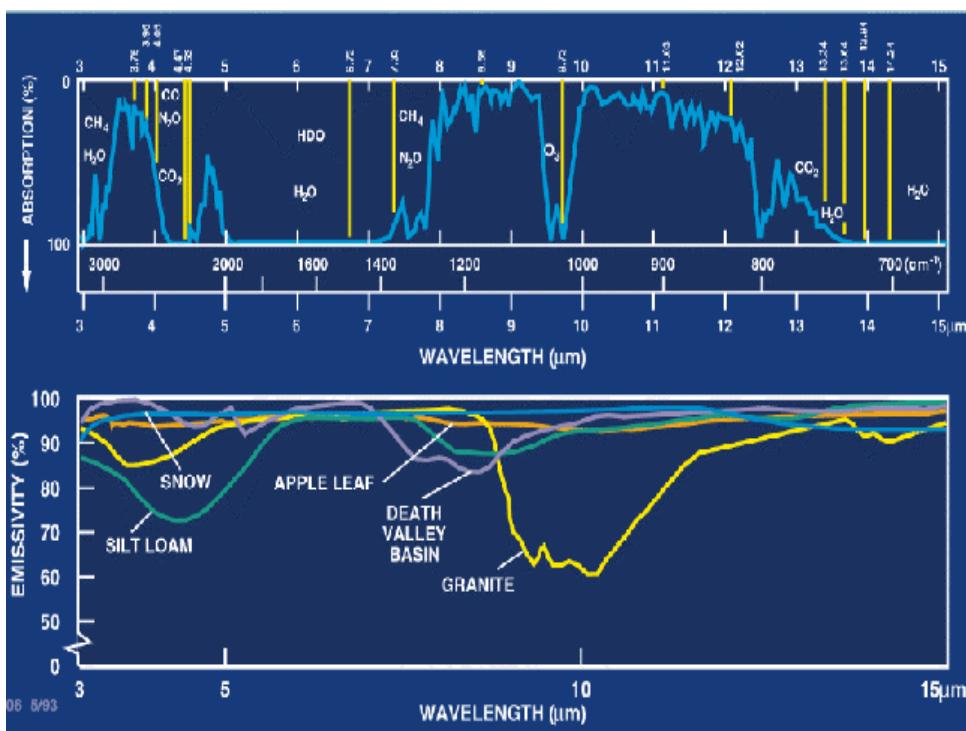

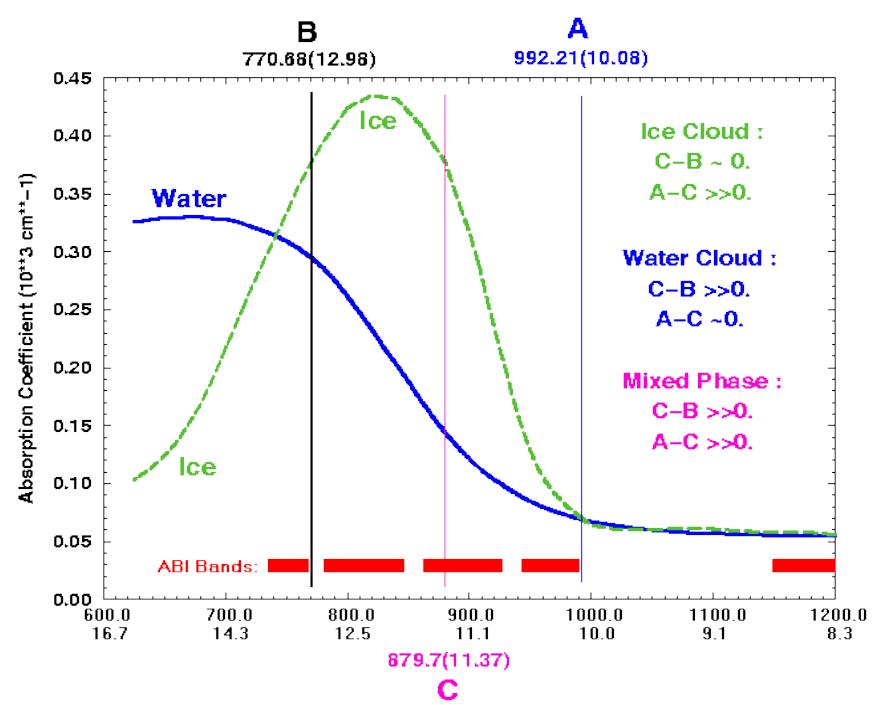

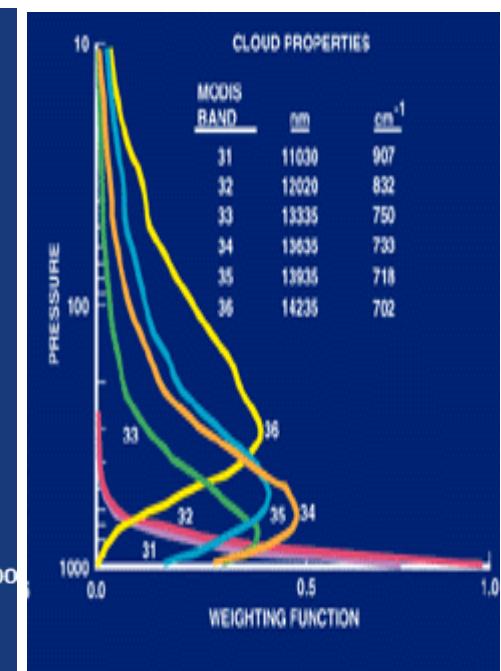

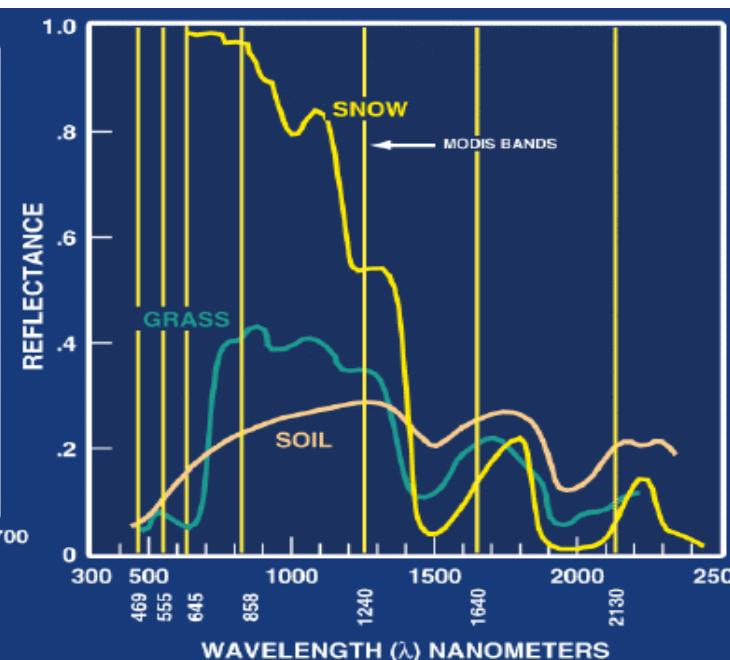

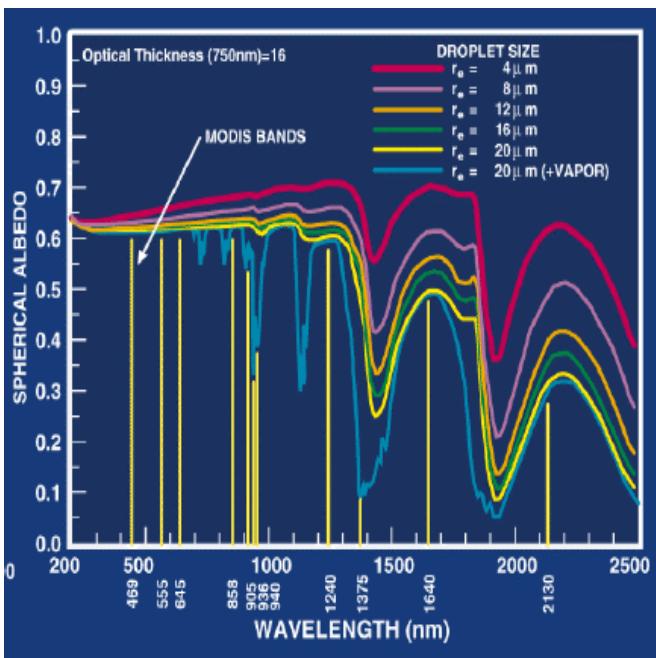

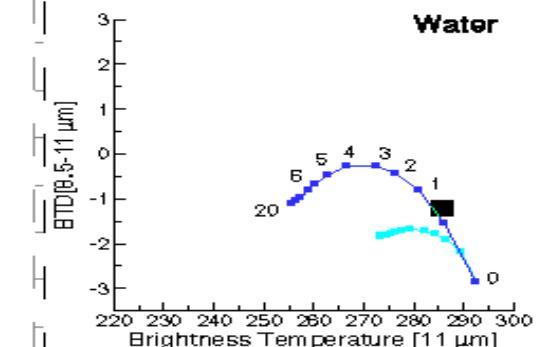

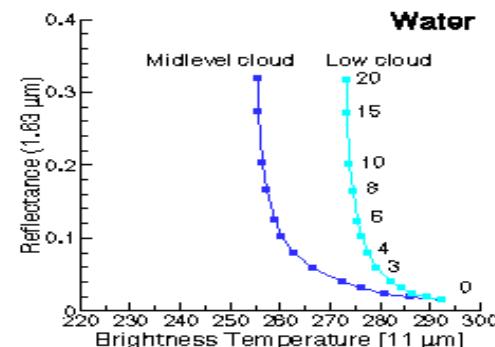

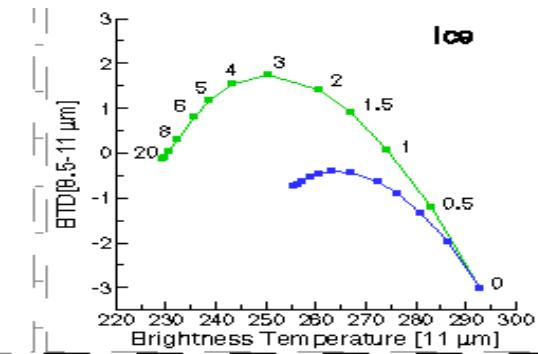

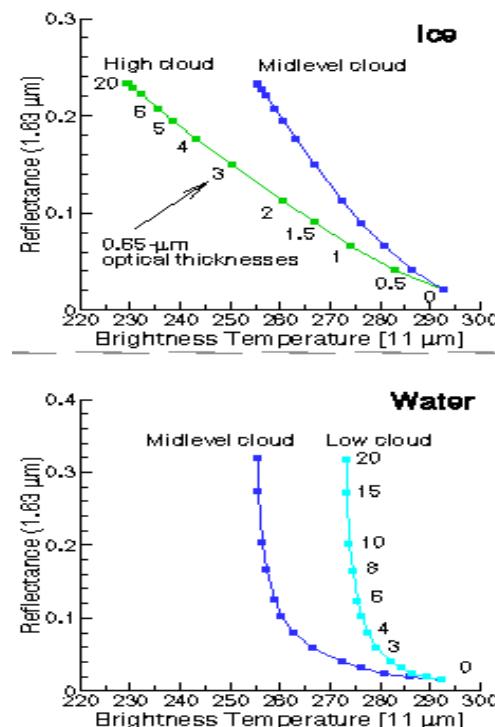

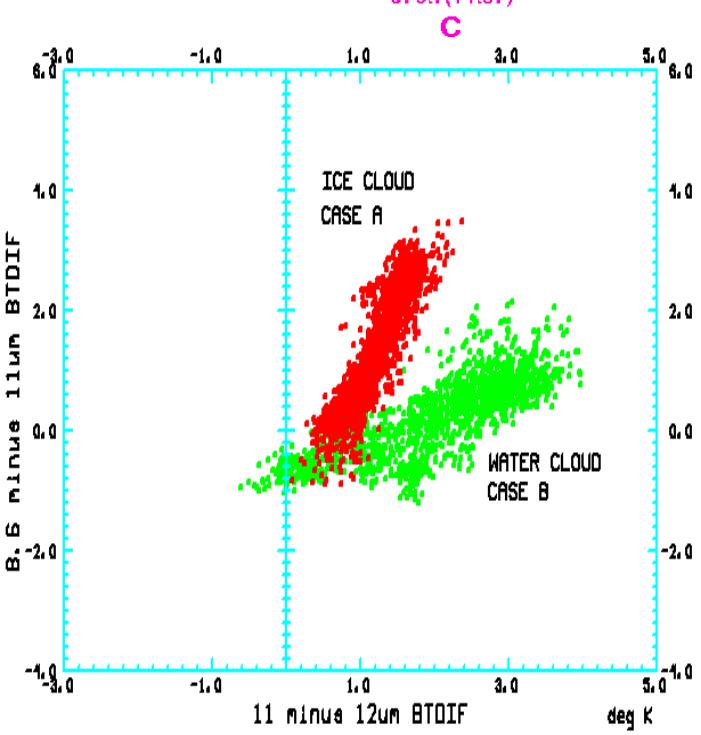

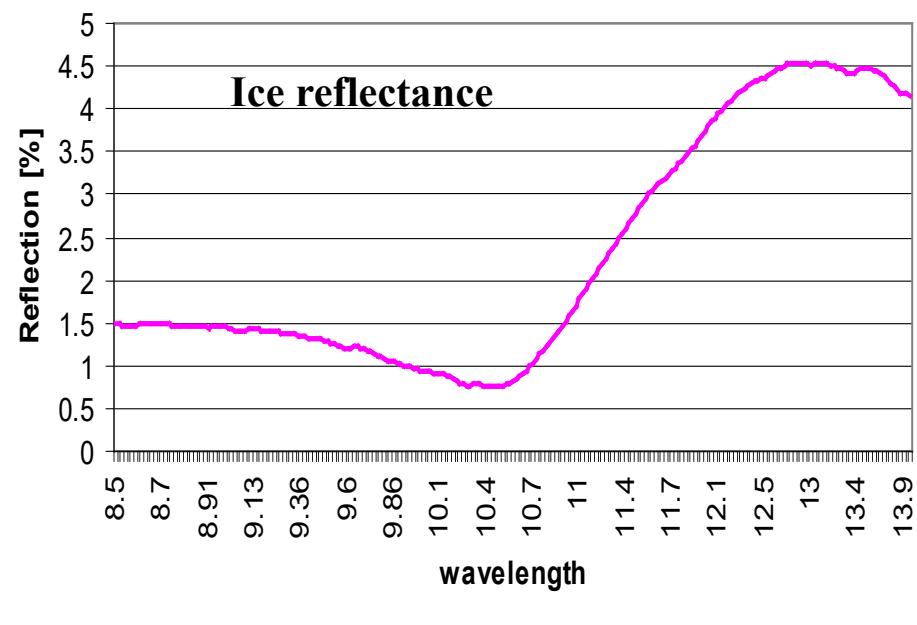

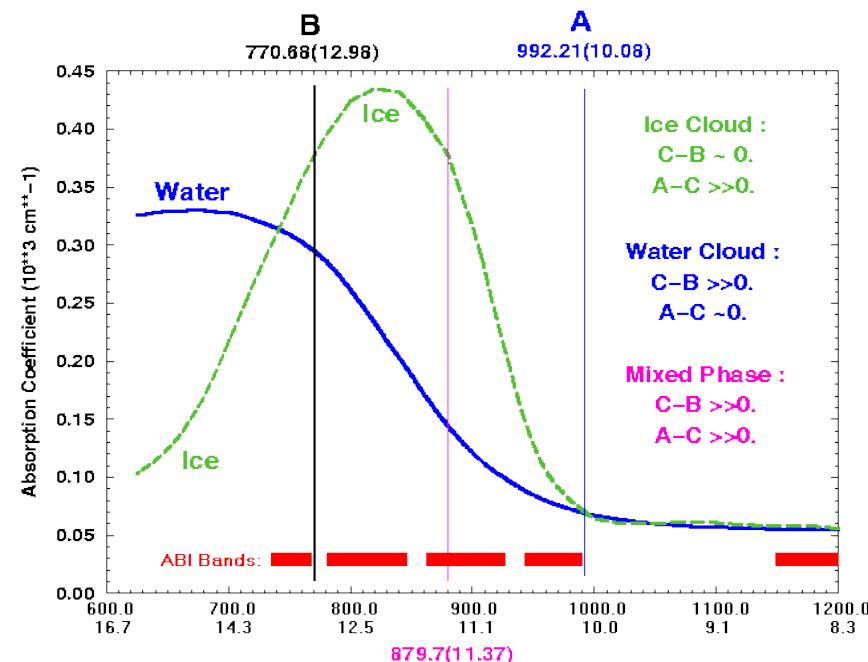

ATMOSPHERE - THERMAL RADIATION

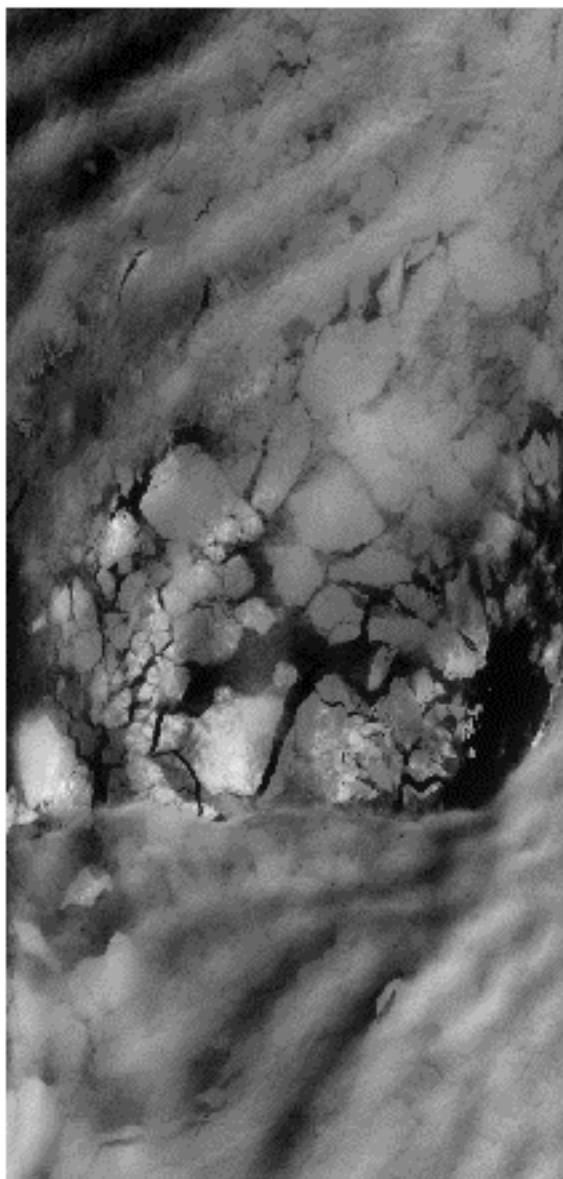

High resolution atmospheric absorption spectrum
and comparative blackbody curves.

Terminology of radiant energy

Definitions of Radiation

QUANTITY	SYMBOL	UNITS
Energy	dQ	Joules
Flux	dQ/dt	Joules/sec = Watts
Irradiance	$dQ/dt/dA$	Watts/meter ²
Monochromatic Irradiance	$dQ/dt/dA/d\lambda$ or $dQ/dt/dA/d\nu$	W/m ² /micron W/m ² /cm ⁻¹
Radiance	$dQ/dt/dA/d\lambda/d\Omega$ or $dQ/dt/dA/d\nu/d\Omega$	W/m ² /micron/ster W/m ² /cm ⁻¹ /ster

Using wavenumbers

Planck's Law

$$B(v, T) = c_1 v^3 / [e^{c_2 v/T} - 1] \quad (\text{mW/m}^2/\text{ster/cm}^{-1})$$

where

v = # wavelengths in one centimeter (cm^{-1})

T = temperature of emitting surface (deg K)

$c_1 = 1.191044 \times 10^{-5}$ ($\text{mW/m}^2/\text{ster/cm}^{-4}$)

$c_2 = 1.438769$ (cm deg K)

Wien's Law

$$dB(v_{\max}, T) / dT = 0 \text{ where } v(\max) = 1.95T$$

indicates peak of Planck function curve shifts to shorter wavelengths (greater wavenumbers) with temperature increase.

$$\text{Stefan-Boltzmann Law} \quad E = \pi \int_0^{\infty} B(v, T) dv = \sigma T^4, \text{ where } \sigma = 5.67 \times 10^{-8} \text{ W/m}^2/\text{deg}^4.$$

states that irradiance of a black body (area under Planck curve) is proportional to T^4 .

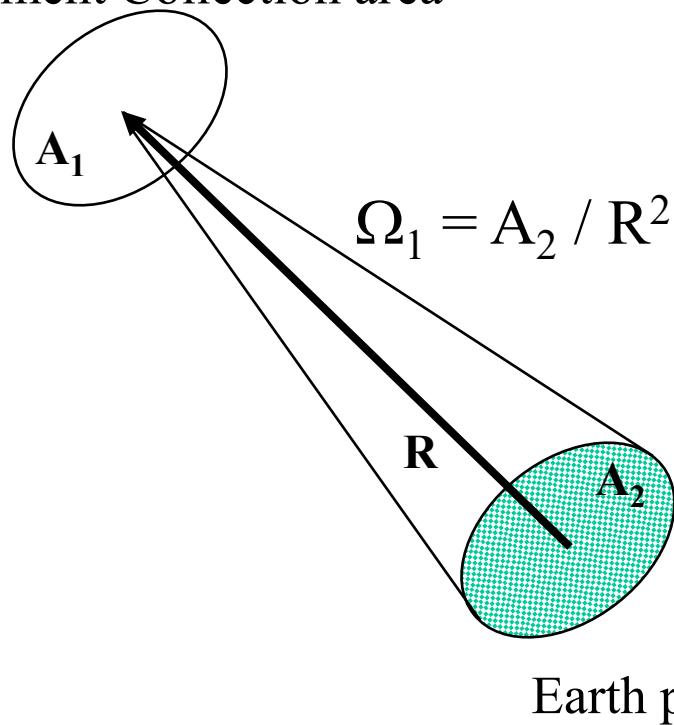

Brightness Temperature

$$T = \frac{c_1 v^3}{B_v} / [\ln(\frac{c_1 v^3}{B_v} + 1)] \text{ is determined by inverting Planck function}$$

Telescope Radiative Power Capture proportional to throughput $A\Omega$

Spectral Power radiated from A_2 to A_1 = $L(v) A_1 \Omega_1$ mW/cm⁻¹

Instrument Collection area

Radiance from surface
= $L(v)$ mW/m² sr cm⁻¹

{Note: $A_1 A_2 / R^2 = A_1 \Omega_1 = A_2 \Omega_2$ }

Radiative Transfer Equation

When reflection from the earth surface is also considered, the RTE for infrared radiation can be written

$$I_\lambda = \varepsilon_\lambda^{\text{sfc}} B_\lambda(T_s) \tau_\lambda(p_s) + \int_{p_s}^{\infty} B_\lambda(T(p)) F_\lambda(p) [d\tau_\lambda(p)/dp] dp$$

where

$$F_\lambda(p) = \{ 1 + (1 - \varepsilon_\lambda) [\tau_\lambda(p_s) / \tau_\lambda(p)]^2 \}$$

The first term is the spectral radiance emitted by the surface and attenuated by the atmosphere, often called the boundary term and the second term is the spectral radiance emitted to space by the atmosphere directly or by reflection from the earth surface.

The atmospheric contribution is the weighted sum of the Planck radiance contribution from each layer, where the weighting function is $[d\tau_\lambda(p)/dp]$. This weighting function is an indication of where in the atmosphere the majority of the radiation for a given spectral band comes from.

RTE in Cloudy Conditions

$$I_{\lambda} = \eta \int_{\lambda} I_{\lambda}^{cd} + (1 - \eta) \int_{\lambda} I_{\lambda}^c \quad \text{where } cd = \text{cloud, } c = \text{clear, } \eta = \text{cloud fraction}$$

$$I_{\lambda}^c = B_{\lambda}(T_s) \tau_{\lambda}(p_s) + \int_{p_s}^0 B_{\lambda}(T(p)) d\tau_{\lambda}.$$

$$\begin{aligned} I_{\lambda}^{cd} &= (1 - \varepsilon_{\lambda}) B_{\lambda}(T_s) \tau_{\lambda}(p_s) + (1 - \varepsilon_{\lambda}) \int_{p_s}^{p_c} B_{\lambda}(T(p)) d\tau_{\lambda} \\ &\quad + \varepsilon_{\lambda} B_{\lambda}(T(p_c)) \tau_{\lambda}(p_c) + \int_{p_c}^0 B_{\lambda}(T(p)) d\tau_{\lambda} \end{aligned}$$

ε_{λ} is emittance of cloud. First two terms are from below cloud, third term is cloud contribution, and fourth term is from above cloud. After rearranging

$$I_{\lambda} - I_{\lambda}^c = \eta \varepsilon_{\lambda} \int_{p_s}^{p_c} \tau(p) \frac{dB_{\lambda}}{dp} dp .$$

Techniques for dealing with clouds fall into three categories: (a) searching for cloudless fields of view, (b) specifying cloud top pressure and sounding down to cloud level as in the cloudless case, and (c) employing adjacent fields of view to determine clear sky signal from partly cloudy observations.

Cloud Properties

RTE for cloudy conditions indicates dependence of cloud forcing (observed minus clear sky radiance) on cloud amount ($\eta\varepsilon_\lambda$) and cloud top pressure (p_c)

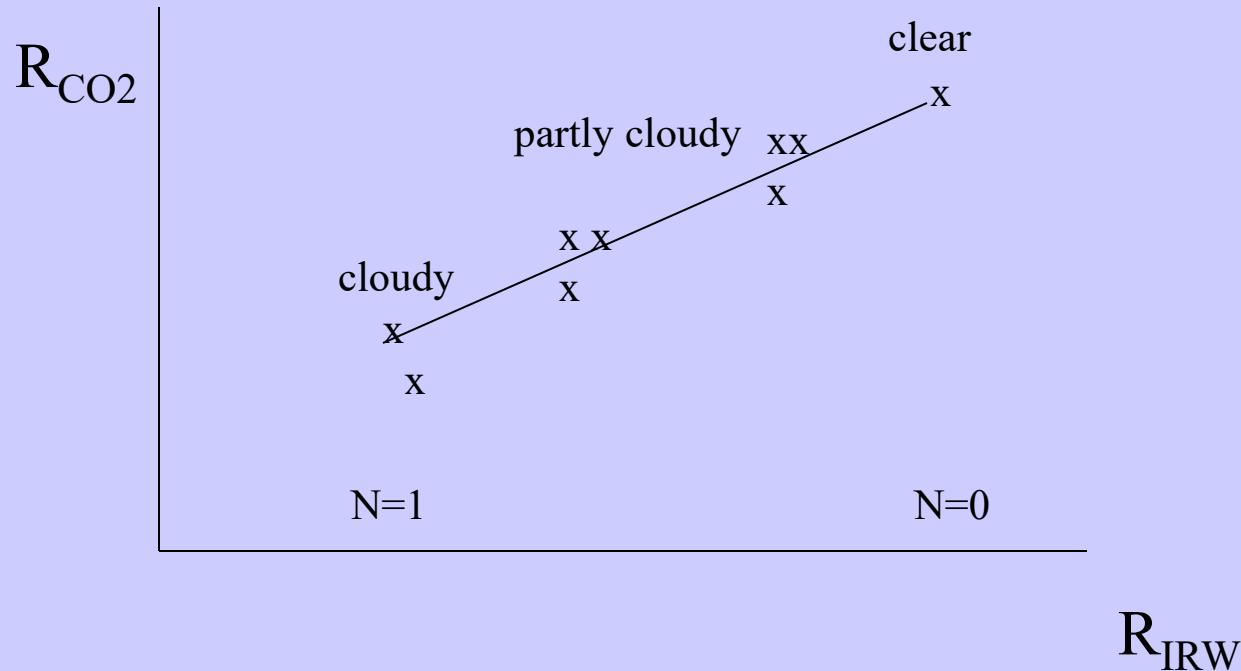

$$(I_\lambda - I_\lambda^{\text{clr}}) = \eta\varepsilon_\lambda \int_{p_s}^{p_c} \tau_\lambda dB_\lambda .$$

Higher colder cloud or greater cloud amount produces greater cloud forcing; dense low cloud can be confused for high thin cloud. Two unknowns require two equations.

p_c can be inferred from radiance measurements in two spectral bands where cloud emissivity is the same. $\eta\varepsilon_\lambda$ is derived from the infrared window, once p_c is known. This is the essence of the CO₂ slicing technique.

Cloud Clearing

For a single layer of clouds, radiances in one spectral band vary linearly with those of another as cloud amount varies from one field of view (fov) to another

Clear radiances can be inferred by extrapolating to cloud free conditions.

Moisture

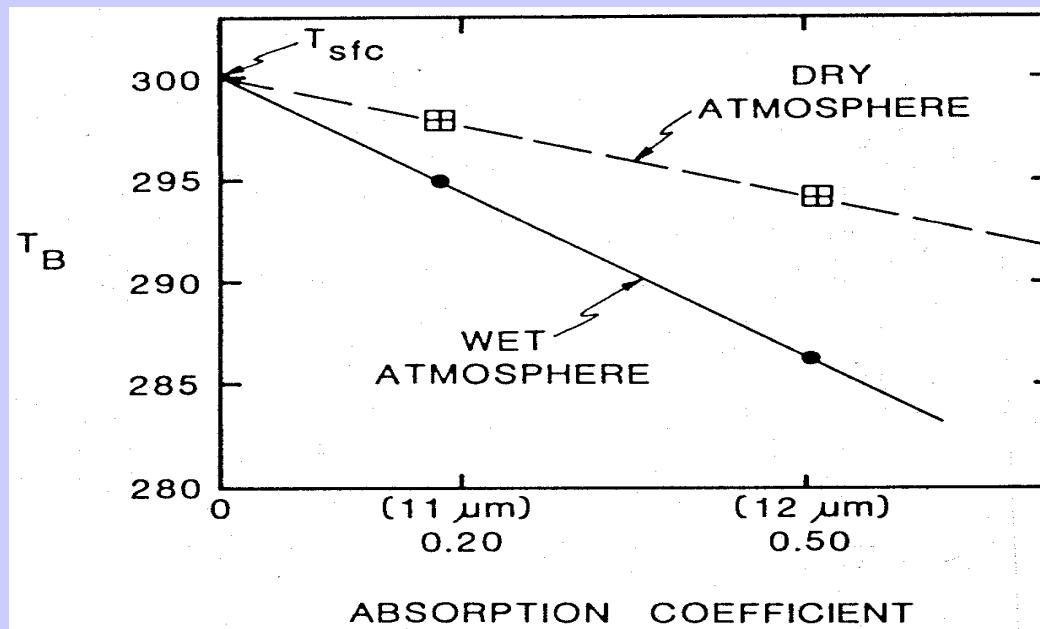

Moisture attenuation in atmospheric windows varies linearly with optical depth.

$$- k_\lambda u$$

$$\tau_\lambda = e^{-k_\lambda u} = 1 - k_\lambda u$$

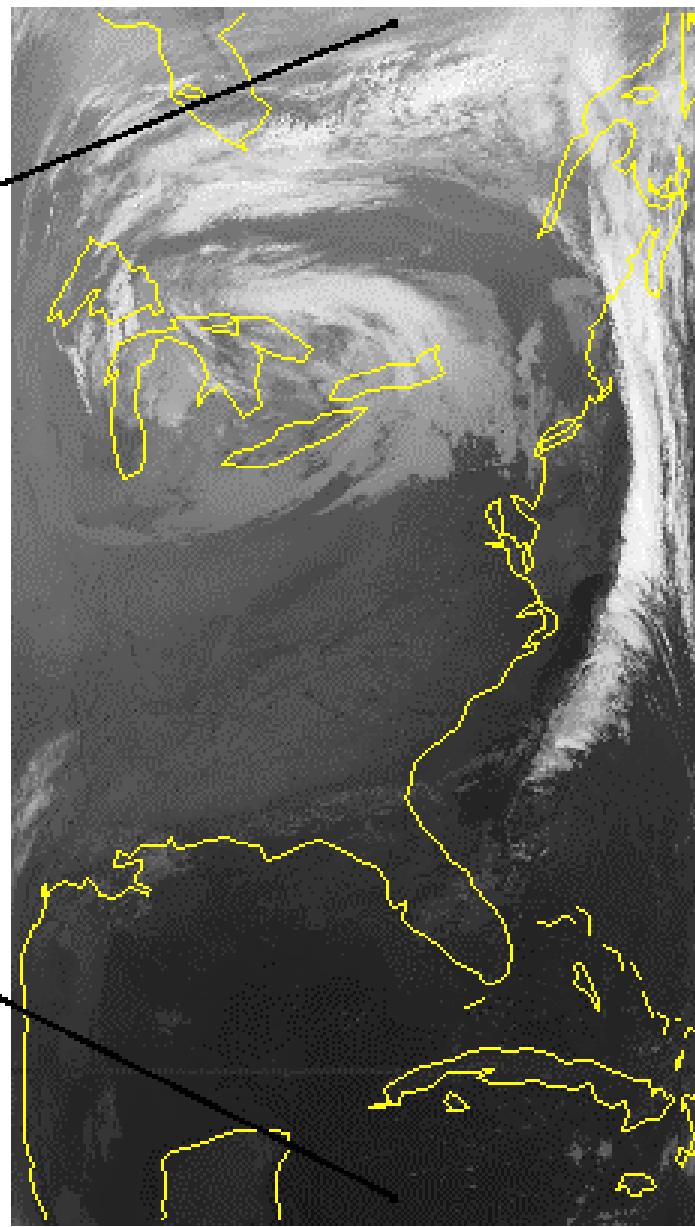

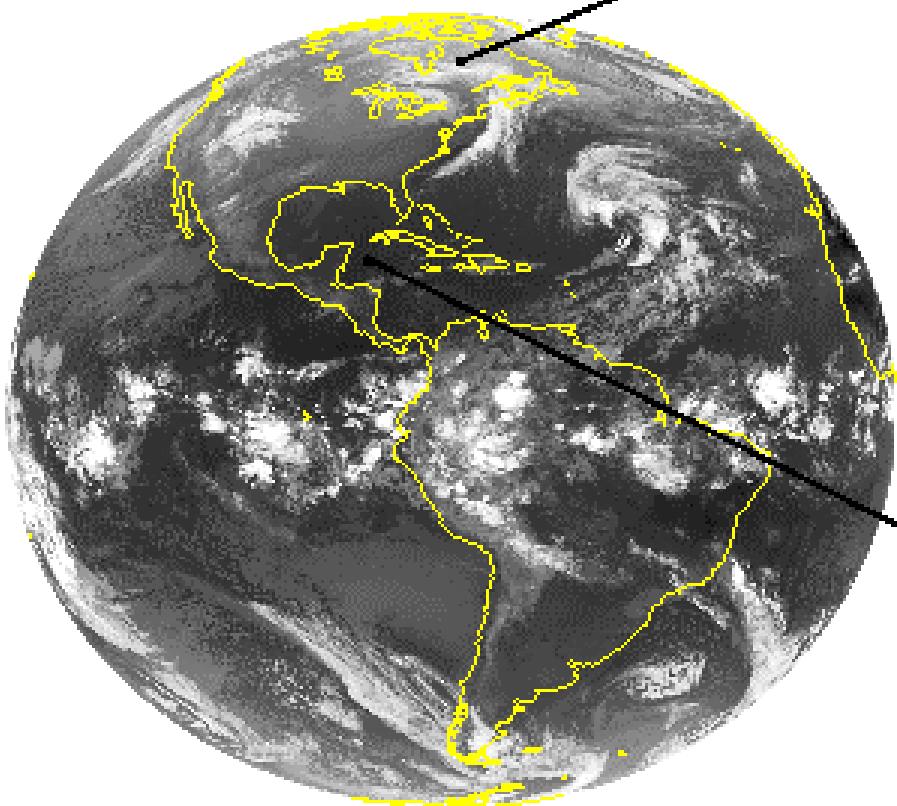

For same atmosphere, deviation of brightness temperature from surface temperature is a linear function of absorbing power. Thus moisture corrected SST can inferred by using split window measurements and extrapolating to zero k_λ

Moisture content of atmosphere inferred from slope of linear relation.

GEO vs LEO

GOES-8 IMAGER 12UTC 02APR98

NOAA-12 AVHRR 12UTC 02APR98

Comparison of geostationary (geo) and low earth orbiting (leo) satellite capabilities

Geo

observes process itself
(motion and targets of opportunity)

repeat coverage in minutes
($\Delta t \leq 30$ minutes)

full earth disk only

best viewing of tropics

same viewing angle

differing solar illumination

visible, IR imager
(1, 4 km resolution)

one visible band

IR only sounder
(8 km resolution)

filter radiometer

diffraction more than leo

Leo

observes effects of process

repeat coverage twice daily
($\Delta t = 12$ hours)

global coverage

best viewing of poles

varying viewing angle

same solar illumination

visible, IR imager
(1, 1 km resolution)

multispectral in visible
(veggie index)

IR and microwave sounder
(17, 50 km resolution)

filter radiometer,
interferometer, and
grating spectrometer

diffraction less than geo
