Radiative Transfer Equation

in the IR

Relevant Material in Applications of Meteorological Satellites

Energy conservation

$$\tau + a + \not{r} = 1$$

R_λ

$r_\lambda R_\lambda$

$a_\lambda R_\lambda = R_\lambda - r_\lambda R_\lambda - \tau_\lambda R_\lambda$

'ENERGY CONSERVATION'

$\tau_\lambda R_\lambda$

$\epsilon_\lambda B_\lambda(T)$

$$\tau + a + r = 1$$

4

Simple case with no atmosphere and opaque cloud

T_c=220 K

$B_\lambda = \varepsilon_\lambda B_\lambda(T_c)$

cloud

$B_\lambda = \varepsilon_\lambda B_\lambda(T_s)$

surface

T_s=300 K
Simple case with no atmosphere and semi-trasparent cloud

$B_\lambda = \varepsilon_\lambda B_\lambda(T_c) + \varepsilon_\lambda B_\lambda(T_s)\,\tau_\lambda)$

$\varepsilon_\lambda = 1 - \tau_\lambda$

$T_c = 220\ K$

$B_\lambda = \varepsilon_\lambda B_\lambda(T_s)$

surface

$T_s = 300\ K$

Radiative Transfer Equation

$$R(n) = B(n,T_o)\mathfrak{C}(n,0)$$

$$+ \int_{z_o}^{z_T} B(n,T[z]) \, (d\mathfrak{C}[n,z]/dz) \, dz$$
Transmittance for Window Channels

$$\tau + a + \cancel{r} = 1$$

τ close to 1
a close to 0

The molecular species in the atmosphere are not very active:
• most of the photons emitted by the surface make it to the Satellite
• if a is close to 0 in the atmosphere then ε is close to 0, not much contribution from the atmospheric layers

Emission, Absorption

Blackbody radiation B_λ represents the upper limit to the amount of radiation that a real substance may emit at a given temperature for a given wavelength.

Emissivity ε_λ is defined as the fraction of emitted radiation R_λ to Blackbody radiation,

$$\varepsilon_\lambda = R_\lambda / B_\lambda \ .$$

In a medium at thermal equilibrium, what is absorbed is emitted (what goes in comes out) so

$$a_\lambda = \varepsilon_\lambda \ .$$

Thus, materials which are strong absorbers at a given wavelength are also strong emitters at that wavelength; similarly weak absorbers are weak emitters.

Transmittance

Transmission through an absorbing medium for a given wavelength is governed by the number of intervening absorbing molecules (path length u) and their absorbing power (k_λ) at that wavelength. Beer's law indicates that transmittance decays exponentially with increasing path length

$$\tau_\lambda \, (z \to \infty) = e^{-k_\lambda u \, (z)}$$

where the path length is given by $\quad u \, (z) = \displaystyle\int_z^\infty \rho \, dz$.

$k_\lambda \, u$ is a measure of the cumulative depletion that the beam of radiation has experienced as a result of its passage through the layer and is often called the optical depth σ_λ.

Realizing that the hydrostatic equation implies $\ g \, \rho \, dz \ = \ - q \, dp$

where q is the mixing ratio and ρ is the density of the atmosphere, then

$$u \, (p) = \int_o^p q \, g^{-1} \, dp \qquad \text{and} \qquad \tau_\lambda \, (p \to o) = e^{-k_\lambda u \, (p)}$$

15 .

Emission, Absorption, Reflection, and Scattering

If a_λ, r_λ, and τ_λ represent the fractional absorption, reflectance, and transmittance, respectively, then conservation of energy says

$$a_\lambda + r_\lambda + \tau_\lambda = 1 \ .$$

For a blackbody $a_\lambda = 1$, it follows that $r_\lambda = 0$ and $\tau_\lambda = 0$ for blackbody radiation. Also, for a perfect window $\tau_\lambda = 1$, $a_\lambda = 0$ and $r_\lambda = 0$. For any opaque surface $\tau_\lambda = 0$, so radiation is either absorbed or reflected $a_\lambda + r_\lambda = 1$.

At any wavelength, strong reflectors are weak absorbers (i.e., snow at visible wavelengths), and weak reflectors are strong absorbers (i.e., asphalt at visible wavelengths).

Radiative Transfer Equation

The radiance leaving the earth-atmosphere system sensed by a satellite borne radiometer is the sum of radiation emissions from the earth-surface and each atmospheric level that are transmitted to the top of the atmosphere. Considering the earth's surface to be a blackbody emitter (emissivity equal to unity), the upwelling radiance intensity, I_λ, for a cloudless atmosphere is given by the expression

$$I_\lambda = \varepsilon_\lambda^{sfc} B_\lambda(T_{sfc}) \tau_\lambda(sfc - top) + \sum_{layers} \varepsilon_\lambda^{layer} B_\lambda(T_{layer}) \tau_\lambda(layer - top)$$

where the first term is the surface contribution and the second term is the atmospheric contribution to the radiance to space.

When reflection from the earth surface is also considered, the Radiative Transfer Equation for infrared radiation can be written

$$I_\lambda = \varepsilon_\lambda{}^{sfc} B_\lambda(T_s) \tau_\lambda(p_s) + \int_{p_s}^{o} B_\lambda(T(p)) F_\lambda(p) [d\tau_\lambda(p)/ dp] dp$$

where
$$F_\lambda(p) = \{ 1 + (1 - \varepsilon_\lambda) [\tau_\lambda(p_s) / \tau_\lambda(p)]^2 \}$$

The first term is the spectral radiance emitted by the surface and attenuated by the atmosphere, often called the boundary term and the second term is the spectral radiance emitted to space by the atmosphere directly or by reflection from the earth surface.
The atmospheric contribution is the weighted sum of the Planck radiance contribution from each layer, where the weighting function is [$d\tau_\lambda(p)$ / dp]. This weighting function is an indication of where in the atmosphere the majority of the radiation for a given spectral band comes from.
